A fully-coupled subwavelength resonance approach to modelling the passive cochlea

Habib Ammari*, Bryn Davies*

Abstract

The aim of this paper is to understand the behaviour of a large number of coupled subwavelength resonators. We use layer potential techniques in combination with numerical computations to study a graded array of subwavelength resonators. This setup is inspired by the small-scale structure of a cochlea. We compute the resonant modes of the system and explore the model’s ability to decompose incoming signals. We also present an explanation for the cochlea’s so-called “travelling wave” behaviour. We do not consider any active elements in this work, choosing instead to thoroughly examine a fully-coupled passive model.

Mathematics subject classification: 35R30, 35C20

Keywords: subwavelength resonance, cochlear mechanics, coupled resonators, hybridisation, passive cochlea, signal processing

1 Introduction

The development of the understanding of the cochlea has largely been a dichotomy between two classes of models [11]. The first, proposed by Ludwig von Helmholtz in the 1850s, are based on resonators tuned to different audible frequencies being distributed along the length of the cochlea [24]. Later, Georg von Békésy demonstrated that when the cochlea is stimulated a wave travels from the base to the apex along the basilar membrane [23]. This discovery won him a Nobel Prize in 1961 and lead to the creation of models based on each receptor cell being excited in sequence as the signal travels through the cochlea.

More recent developments have put Helmholtz’ resonance model back in the spotlight by identifying bundles of cells known as inner hair cells as candidate resonant elements. These cells are about 10µm tall and are distributed along the basilar membrane increasing in size from base to apex [1, 16]. It is now known that the displacement of a hair cell bundle leads to a change in the

*Department of Mathematics, ETH Zürich, Rämistrasse 101, CH-8092 Zürich, Switzerland (habib.ammari@sam.math.ethz.ch, bryn.davies@sam.math.ethz.ch).
distribution of electrical charge in the cell membrane [18], offering a mechanism for the production of a signal in the auditory nerve.

It is also known that the cochlea is an active organ and emits sounds (known as otoacoustic emissions) as part of its response to a signal [19, 20, 14]. We shall only consider a passive system of resonators here, but will present a model that can be readily modified to include active elements in future work.

In this paper, we apply boundary integral techniques to understand the complex interactions between the hair cell bundles [5, 10]. The mathematical complexity of the hybridisation between a large number of coupled resonators has been the main barrier to developing Helmholtz’ resonance models. A human cochlea has around 3500 inner hair cells and is approximately 30mm long [21]. Compare this to the wavelength of audible sound (a few centimetres to several metres) and it is clear that complex interactions will occur between the resonant elements.

In order to find the eigenmodes of the system of hybridised resonators, we employ methods based on the assumption that there is a high contrast between both the bulk moduli and the density of the cell bundles and the fluid they are surrounded by. Similar techniques have previously been applied to other high-contrast materials that exhibit subwavelength resonance, the classical example being the Minnaert resonance of air bubbles in water [3, 5]. This analysis (in Section 2.2 & 2.3) relies on the use of layer potential techniques [4, 9, 7].

It is found that a graded array of hybridised resonators has a set of resonant frequencies that becomes increasingly dense (within a finite range) as the number of resonators is increased. We study the eigenmodes and present a scheme (in Section 2.4) for how the model processes incoming signals, filtering them into the system’s resonant frequencies. Finally, in Section 2.5 we present the significant observation that our (resonance) model predicts the existence of a travelling wave, as observed by Békésy.

2 Response of the coupled resonators

2.1 Preliminaries

We consider a domain $D$ in $\mathbb{R}^2$ which is the disjoint union of $N \in \mathbb{N}$ bounded and simply connected subdomains $\{D_1, \ldots, D_N\}$ such that, for each $n = 1, \ldots, N$, there is $0 < s < 1$ so that $\partial D_n \in C^{1,s}$. These disjoint subdomains represent the $N$ hair cell bundles. We will consider the bundles arranged in a straight line since the curvature of the cochlea does not contribute to its mechanical behaviour [16]. Figure 1 shows an example of such an arrangement (in the special case of circular subdomains, which we will consider from Section 2.3 onwards).

We denote by $\rho_b$ and $\kappa_b$ the density and bulk modulus of the interior of the cell bundles, respectively, and denote by $\rho$ and $\kappa$ the corresponding parameters for the auditory fluid (which we assume occupies $\mathbb{R}^2 \setminus \overline{D}$).

We consider the problem of an incident wave $p^{in}(x, t)$ that is scattered by
Figure 1: An array of eight (circular) graded subdomains $D = D_1 \cup \cdots \cup D_8$ arranged linearly along $x_2 = 0$.

$D$. This is given by

$$
\begin{align*}
\begin{cases}
\nabla \cdot \frac{1}{\rho} \nabla - \frac{1}{\kappa} \frac{\partial^2}{\partial t^2} p = 0, & \text{for } (x,t) \in \mathbb{R}^2 \setminus \overline{D} \times \mathbb{R}, \\
\nabla \cdot \frac{1}{\rho_b} \nabla - \frac{1}{k_b} \frac{\partial^2}{\partial t^2} p = 0, & \text{for } (x,t) \in D \times \mathbb{R}, \\
p_+ - p_- = 0, & \text{for } (x,t) \in \partial D \times \mathbb{R}, \\
\frac{1}{\rho} \frac{\partial p}{\partial x} \bigg|_+ - \frac{1}{\rho_b} \frac{\partial p}{\partial x} \bigg|_- = 0, & \text{for } (x,t) \in \partial D \times \mathbb{R}, \\
p^* := p - p^{in} = 0, & \text{for } x \in \mathbb{R}^2, t \ll 0,
\end{cases}
\end{align*}
$$

(1)

where $\frac{\partial}{\partial x}$ denotes the outward normal derivative in $x$ and the subscript $+$ and $-$ are used to denote evaluation from outside and inside $\partial D$ respectively.

We then introduce the auxiliary parameters

$$
v = \sqrt{\frac{\kappa}{\rho}}, \quad v_b = \sqrt{\frac{k_b}{\rho_b}}, \quad k = \frac{\omega}{v}, \quad k_b = \frac{\omega}{v_b},
$$

which are the wave speeds and wavenumbers in $\mathbb{R}^2 \setminus \overline{D}$ and in $D$ respectively. We also introduce the two dimensionless contrast parameters

$$
\delta = \frac{\rho_b}{\rho}, \quad \tau = \frac{k_b}{k} = \frac{v_b}{v} = \frac{\rho_b k}{\rho_b k},
$$

(2)

By rescaling the dimensions of the physical problem we can assume that

$$
v = O(1), \quad v_b = O(1), \quad \tau = O(1).
$$

(3)

We also assume that the rescaled dimensions are such that the subdomains $\{D_1, \ldots, D_N\}$ have widths that are $O(1)$. On the other hand, we assume that there is a large contrast between the bulk moduli, so that

$$
\delta \ll 1.
$$

(4)

We transform problem (1) into the frequency domain by taking the Fourier transform $u(x, \omega) := \int_{-\infty}^{\infty} p(x,t)e^{i\omega t} \, dt$ to reach

$$
\begin{align*}
\begin{cases}
(\Delta + k^2) u(x, \omega) = 0, & \text{in } \mathbb{R}^2 \setminus \overline{D}, \\
(\Delta + k_b^2) u(x, \omega) = 0, & \text{in } D, \\
u_+ - u_- = 0, & \text{on } \partial D, \\
\delta \frac{\partial u}{\partial x} \bigg|_+ - \frac{\partial u}{\partial x} \bigg|_- = 0, & \text{on } \partial D, \\
u^* := u - u^{in} \text{ satisfies the SRC, as } |x| \to \infty.
\end{cases}
\end{align*}
$$

(5)
‘SRC’ is used to denote the Sommerfeld radiation condition

$$\lim_{|x| \to \infty} |x|^{1/2} \left( \frac{\partial}{\partial |x|} - ik \right) u(x, \omega) = 0.$$  

(6)

The SRC is the condition required to ensure that we select the solution that is outgoing (rather than incoming from infinity) and gives the well-posedness of problem (5).

We wish to use layer potential representations for the solutions to the scattering problem (5).

**Definition 2.1.** We define the Helmholtz single layer potential associated with the domain $D$ and wavenumber $k$ as

$$S^k_D[\varphi](x) := \int_{\partial D} \Gamma^k(x - y) \varphi(y) \, d\sigma(y), \quad x \in \partial D, \varphi \in L^2(\partial D),$$  

(7)

where $\Gamma^k$ is the outgoing (i.e. satisfying the SRC) fundamental solution to the Helmholtz operator $\Delta + k^2$ in $\mathbb{R}^2$. We similarly define the Neumann-Poincaré operator associated with $D$ and $k$ as

$$K^k_{D,*}[\varphi](x) = \int_{\partial D} \frac{\partial \Gamma^k(x - y)}{\partial n_x} \varphi(y) \, d\sigma(y), \quad x \in \partial D, \varphi \in L^2(\partial D).$$  

(8)

We can then represent the solution to (5) as

$$u = \begin{cases} u^{in}(x) + S^k_D[\psi](x), \quad x \in \mathbb{R}^2 \setminus D, \\ S^k_D[\phi](x), \quad x \in D, \end{cases}$$  

(9)

for some surface potentials $(\phi, \psi) \in L^2(\partial D) \times L^2(\partial D)$.

We define the space $H^1(\partial D) := \{ u \in L^2(\partial D) : \nabla u \in L^2(\partial D) \}$ in the usual way and use $Id$ to denote the identity on $L^2(\partial D)$. Then, using the representation (9), problem (5) is equivalent [7, 9] to finding $(\phi, \psi) \in L^2(\partial D) \times L^2(\partial D)$ such that

$$A(\omega, \delta) \begin{pmatrix} \phi \\ \psi \end{pmatrix} = \begin{pmatrix} u^{in} \\ \delta \frac{\partial u^{in}}{\partial n_x} \end{pmatrix},$$  

(10)

where

$$A(\omega, \delta) := \begin{bmatrix} S^k_D \\ -\frac{1}{2} Id + K^k_{D,*} \end{bmatrix} \begin{bmatrix} -S^k_D \\ -\delta \frac{1}{2} Id + K^k_{D,*} \end{bmatrix}. $$  

(11)

We now recall from e.g. [3, 4] the main result that will allow us to understand the leading order behaviour of $A$ in (10).

**Lemma 2.2.** In the space $\mathcal{L}(L^2(\partial D) \times L^2(\partial D), H^1(\partial D) \times L^2(\partial D))$ we have

$$A(\omega, \delta) = A_0 + \omega^2 \ln \omega A_{1,1,0} + \omega^2 A_{1,2,0} + \delta A_{0,1} + O(\delta \omega^2 \ln \omega) + O(\omega^4 \ln \omega),$$

4
where

\[
A_0 := \begin{bmatrix}
-\frac{1}{2} I_d + \mathcal{K}_D & -\hat{S}_D \\
\hat{S}_D & 0
\end{bmatrix}, \quad A_{1,1,0} := \begin{bmatrix}
v_b^{-2}S_{D,1}^{(1)} & -v^{-2}S_{D,1}^{(1)} \\
v_b^{-2}K_{D,1}^{(1)} & 0
\end{bmatrix},
\]

\[
A_{1,2,0} := \begin{bmatrix}
v_b^{-2}(-\ln v_b S_{D,1}^{(1)} + S_{D,1}^{(2)}) & -v^{-2}(-\ln v S_{D,1}^{(1)} + S_{D,1}^{(2)}) \\
v_b^{-2}(-\ln v_b K_{D,1}^{(1)} + K_{D,1}^{(2)}) & 0
\end{bmatrix},
\]

and

\[
A_{0,1} := \begin{bmatrix}
0 & 0 \\
0 & -(\frac{1}{2} I_d + \mathcal{K}_D)
\end{bmatrix}.
\]

The above operators are defined as

\[
\mathcal{S}_D[\phi](x) := \frac{1}{2\pi} \int_{\partial D} \ln|x-y|\phi(y) \, d\sigma(y),
\]

\[
\hat{S}_D[\phi](x) := \mathcal{S}_D[\phi](x) + \eta_k \int_{\partial D} \phi \, d\sigma, \quad \eta_k := \frac{1}{2\pi}(\ln k + \gamma - \ln 2) - \frac{i}{4},
\]

\[
S_{D,1}^{(1)}[\phi](x) := \int_{\partial D} b_1 |x-y|^2\phi(y) \, d\sigma(y),
\]

\[
S_{D,1}^{(2)}[\phi](x) := \int_{\partial D} b_1 |x-y|^2 \ln|x-y|\phi(y) + c_1 |x-y|^2 \phi(y) \, d\sigma(y),
\]

\[
K_{D,1}^{(1)}[\phi](x) := \int_{\partial D} b_1 \frac{\partial |x-y|^2}{\partial \nu(x)}\phi(y) \, d\sigma(y),
\]

\[
K_{D,1}^{(2)}[\phi](x) := \int_{\partial D} b_1 \frac{\partial |x-y|^2 \ln|x-y|}{\partial \nu(x)}\phi(y) + c_1 \frac{\partial |x-y|^2}{\partial \nu(x)}\phi(y) \, d\sigma(y),
\]

where \( b_1 := -\frac{1}{8\pi}, c_1 := -\frac{1}{8\pi}(\gamma - \ln 2 - 1 - \frac{i}{4}) \) and \( \gamma = 0.5772\ldots \) is the Euler constant.

The operator \( \mathcal{S}_D \) is the Laplace single layer potential associated with \( D \). Since we are working in two dimensions this is not generally invertible however the following two lemmas help us understand the extent of its degeneracy.

**Lemma 2.3.** If for some \( \phi \in L^2(\partial D) \) with \( \int_{\partial D} \phi = 0 \) it holds that \( \mathcal{S}_D[\phi](x) = 0 \) for all \( x \in \partial D \), then \( \phi = 0 \) on \( \partial D \).

**Proof.** The arguments given in [8, Lemma 2.25] can be easily generalised to the case where \( D \) is the disjoint union of a finite number of bounded Lipschitz domains in \( \mathbb{R}^2 \).

**Proposition 2.4.** Independent of the number \( N \in \mathbb{N} \) of connected components making up \( D \), we have that

\[ \dim \ker \mathcal{S}_D \leq 1. \]
Proof. Let \( \psi \in \ker S_D \). Then by Lemma 2.3 if \( \int_{\partial D} \psi = 0 \) then \( \psi = 0 \). Suppose that \( \int_{\partial D} \psi \neq 0 \) then take \( \tilde{\psi} \in \ker S_D \) with \( \int_{\partial D} \tilde{\psi} \neq 0 \) and then consider the function

\[
f = \frac{\psi}{\int_{\partial D} \psi} - \frac{\tilde{\psi}}{\int_{\partial D} \tilde{\psi}}.
\]

Then \( f \) satisfies \( S_D[f] = 0 \) and \( \int_{\partial D} f = 0 \) so by Lemma 2.3 we have that \( f = 0 \). Therefore \( \psi = (\int_{\partial D} \psi/ \int_{\partial D} \tilde{\psi}) \tilde{\psi} \). □

There are two cases to consider, in light of Proposition 2.4:

- Case I: \( \dim \ker S_D = 1 \),
- Case II: \( \dim \ker S_D = 0 \).

By the Fredholm Alternative Theorem, an equivalent formulation is

- Case I: \( S_D \) is not invertible,
- Case II: \( S_D \) is invertible.

as an operator in \( L(L^2(\partial D), H^1(\partial D)) \). We are now in a position to prove an important property of the operator \( \hat{S}_D^k \) that was defined in Lemma 2.2 and is the leading order approximation to \( S_D^k \).

**Lemma 2.5.** For any fixed \( k \in \mathbb{C}\setminus\{0\} \), \( \hat{S}_D^k \) is invertible in \( L(L^2(\partial D), H^1(\partial D)) \).

Proof. Since \( \hat{S}_D^k \) is Fredholm with index 0 we need only to show that it is injective. To this end, assume that \( y \in L^2(\partial D) \) is such that

\[
\hat{S}_D^k[y] = S_D[y] + \eta_k \int_{\partial D} y = 0.
\]

(12)

**Case I:** Let \( \psi_0 \) be the unique element of \( \ker S_D \) with \( \int_{\partial D} \psi_0 = 1 \) (which exists as a result of Lemma 2.3). We then find that \( S_D[y] \perp \psi_0 \) in \( L^2(\partial D) \) and hence (12) becomes

\[
\eta_k \left( \int_{\partial D} y \right) \left( \int_{\partial D} \psi_0 \right) = 0.
\]

Thus \( \int_{\partial D} y = 0 \). It follows from (12) that \( S_D[y] = 0 \) and further by Lemma 2.3 we have that \( y = 0 \).

**Case II:** Define \( \psi_0 = S_D^{-1}(1) \) then (12) gives us that

\[
S_D[y] = -\eta_k \int_{\partial D} y,
\]

is constant so, since \( S_D \) is injective, we find that \( y = c\psi_0 \) for some \( c \). Substituting back into (12) gives

\[
c + \eta_k c \int_{\partial D} \psi_0 = 0.
\]

Everything here is real with the one exception of \( \eta_k \) (which has nonzero imaginary part) so we must have that \( c = 0 \). □
2.2 Resonant modes

**Definition 2.6.** For a fixed $\delta$ we define a resonant frequency to be $\omega \in \mathbb{C}$ with positive real part and negative imaginary part such that there exists a nontrivial solution to

$$A(\omega, \delta) \begin{pmatrix} \phi \\ \psi \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

where $A(\omega, \delta)$ is defined in (11). For each resonant frequency $\omega$ we define the corresponding eigenmode (or resonant mode or normal mode) as

$$u = \begin{cases} S_{D}[\psi](x), & x \in \mathbb{R}^2 \setminus D, \\ S_{D}^{b}[\phi](x), & x \in D. \end{cases}$$

**Remark 2.7.** The reason for the choices of sign in Definition 2.6 is to give a physical meaning to a complex resonant frequency. The real part represents the frequency of oscillation and the imaginary part describes the rate of attenuation (hence it should be negative, to give a solution that decays over time).

**Remark 2.8.** The interpretation of Definition 2.6 is that resonant modes are modes of vibration that can (theoretically) occur without the input of energy. We see from Figure 4 that this definition is equivalent to the notion that resonant frequencies are those at which the system will oscillate at much greater amplitude than is generally the case.

Manipulating the first entry of (13) we find that

$$\hat{S}_{D}^{b}[\phi] - \hat{S}_{D}^{b}[\psi] = \hat{S}_{D}^{b}[\phi - \psi] + \frac{1}{2\pi} \ln \frac{v}{v_{b}} \int_{\partial D} \phi,$$

hence

$$\psi = \phi + \frac{1}{2\pi} \ln \frac{v}{v_{b}} \left( \int_{\partial D} \phi \right) (\hat{S}_{D}^{b})^{-1}[\chi_{\partial D}] + O(\omega^2),$$

since an application of $(\hat{S}_{D}^{b})^{-1}$ rescales like $O(1/\ln \omega)$. Here, $\chi_{\partial D}$ is used to denote the characteristic function of $\partial D$.

To deal with the second component of (13) we first prove some technical lemmas.

**Lemma 2.9.** For any $\phi \in L^2(\partial D)$ and $j = 1, \ldots, N$, we have that

(i) $\int_{\partial D_{j}} (\frac{1}{2} I - \mathcal{K}_{D_{j}})[\phi] = 0,$

(ii) $\int_{\partial D_{j}} (\frac{1}{2} I + \mathcal{K}_{D_{j}})[\phi] = \int_{\partial D_{j}} \phi.$

**Proof.** (i) follows from the jump relations for single layer potentials and the fact $\mathcal{S}_{D}[\phi]$ is harmonic in $D$ [9, 8]. Then (ii) is immediate. \hfill \Box

**Lemma 2.10.** For any $\phi \in L^2(\partial D)$ and $j = 1, \ldots, N$, we have that

(i) $\int_{\partial D_{j}} \mathcal{K}_{D_{j},1}^{(1)}[\phi] = 4b_{1}|D_{j}| \int_{\partial D} \phi,$

(ii) $\int_{\partial D_{j}} \mathcal{K}_{D_{j}}^{(2)}[\phi] = - \int_{D_{j}} \mathcal{S}_{D}[\phi] + (4b_{1} + 4c_{1})|D_{j}| \int_{\partial D} \phi,$

where $|D_{j}|$ is the area of $D_{j}$.
Proof. (i) follows from the divergence theorem
\[
\int_{\partial D_j} K_{D,1}^{(1)}[\phi](x) d\sigma(x) = b_1 \int_{D_j} \int_{\partial D} \Delta_x |x-y|^2 \phi(y) d\sigma(y) dx
= 4b_1 |D_j| \int_{\partial D} \phi(y) d\sigma(y).
\]

Similarly for (ii) we can show that
\[
\int_{\partial D_j} K_{D,1}^{(2)}[\phi](x) d\sigma(x) = \int_{D_j} \int_{\partial D} \Delta_x |x-y|^2 (b_1 \ln |x-y| + c_1) \phi(y) d\sigma(y) dx
= -\int_{\partial D} \mathcal{S}_D[\phi](x) dx + (4b_1 + 4c_1)|D_j| \int_{\partial D} \phi(y) d\sigma(y),
\]
making use of the fact that \(b_1 = -1/8\pi\).

Turning now to the second component of (13) we see that
\[
\left(-\frac{1}{2} I_d + \mathcal{K}_D + v_b^{-2} \mathcal{K}_{D,1}^{(1)} \omega^2 \ln \omega + v_b^{-2} (-\ln v_b \mathcal{K}_{D,1}^{(1)} + \mathcal{S}_{D,1}^{(2)} \omega^2) \right)[\phi]
- \delta \left(\frac{1}{2} I_d + \mathcal{K}_D^*\right)[\phi] = O(\delta \omega^2 \ln \omega) + O(\omega^4 \ln \omega).
\]

We substitute expression (15) for \(\psi\) to see that \(\phi\) satisfies the equation
\[
\left(-\frac{1}{2} I_d + \mathcal{K}_D^*\right)[\phi] + \left(v_b^{-2} \mathcal{K}_{D,1}^{(1)} \omega^2 \ln \omega + v_b^{-2} (-\ln v_b \mathcal{K}_{D,1}^{(1)} + \mathcal{S}_{D,1}^{(2)} \omega^2) \right)[\phi]
- \delta \left(\frac{1}{2} I_d + \mathcal{K}_D^*\right)[\phi] - \frac{1}{2\pi} \delta \ln \frac{v}{v_b} \left(\int_{\partial D} \phi \right) \left(\frac{1}{2} I_d + \mathcal{K}_D\right) \left([\mathcal{S}_D^*]^{-1}[\chi_{\partial D}]\right) = O(\delta \omega^2 \ln \omega) + O(\omega^4 \ln \omega).
\]

At leading order (16) is just \((-\frac{1}{2} I_d + \mathcal{K}_D^*))[\phi] = 0\) so it would be useful to understand this kernel, which we achieve with the following two lemmas.

**Lemma 2.11.** If \(\phi \in L^2(\partial D)\) is such that \(\phi \in \text{ker}(-\frac{1}{2} I_d + \mathcal{K}_D^*)\) then there exist constants \(b_j\) such that \(\mathcal{S}_D[\phi] = \sum_{j=1}^N b_j \chi_{\partial D_j}\).

**Proof.** Let \(u := \mathcal{S}_D[\phi]\). Then \(\Delta u = 0\) in \(D\) and \(\frac{\partial u}{\partial n} = 0\) on \(\partial D\) (known as a “jump condition”)\) [7, 9] so \(u\) satisfies a homogeneous interior Neumann problem on each of the \(N\) connected components \(D_1, \ldots, D_N\) of \(D\). It is known that such problems are uniquely solvable up to the addition of a constant.

**Lemma 2.12.** Fix some \(k_0 \in \mathbb{C} \setminus \{0\}\). The set of vectors \(\{\psi_1, \ldots, \psi_N\}\) defined as
\[
\psi_i := \left(\mathcal{S}_D^{k_0}\right)^{-1}[\chi_{\partial D_i}],
\]
forms a basis for the space \(\text{ker}(-\frac{1}{2} I_d + \mathcal{K}_D^*)\).
Proof. The linear independence of \( \{ \psi_1, \ldots, \psi_N \} \) follows from the linearity and injectivity of \( \hat{S}_D^{k_0} \), plus the independence of \( \{ X_{\partial D_1}, \ldots, X_{\partial D_N} \} \).

For \( \phi \in L^2(\partial D) \) the difference between \( \hat{S}_D^{k_0}[\phi](x) \) and \( S_D[\phi](x) \) is a constant (in \( x \)) so they will have the same derivatives. In particular, they are both harmonic and satisfy the same jump conditions across \( \partial D \). Therefore, using arguments as in Lemma 2.11, we see that if \( \phi \in \ker(\frac{1}{2} \text{Id} + K^*_D) \) then \( \hat{S}_D^{k_0}[\phi] \in \text{span}\{ X_{\partial D_1}, \ldots, X_{\partial D_N} \} \). Thus \( \phi \in \text{span}\{ \psi_1, \ldots, \psi_N \} \).

From Lemma 2.12 we know that \( \ker(\frac{1}{2} \text{Id} + K^*_D) \) has dimension equal to the number of connected components of \( D \) (a wider discussion can be found in e.g. [2]). Thus we can take a basis

\[
\{ \phi_1, \ldots, \phi_N \}.
\]

of the null space \( \ker(\frac{1}{2} \text{Id} + K^*_D) \). Then, in light of the fact that at leading order (16) is just \( (\frac{1}{2} \text{Id} + K^*_D)[\phi] = 0 \), it is natural to seek a solution of the form

\[
\phi = \sum_{j=1}^N a_j \phi_j + O(\omega^2 \ln \omega + \delta),
\]

for some non-trivial constants \( a_j \) with \( \sum_j |a_j| = O(1) \). The solutions \( (\phi, \psi) \) to (13) are determined only up to multiplication by a constant (and hence so are \( a_1, \ldots, a_N \)). We fix the scaling to be such that the eigenmodes are normalised in the \( L^2(D) \)-norm

\[
||u||_{L^2(D)}^2 = \int_D |S_D^{k_0}[\phi]|^2 = 1.
\]

We now integrate (16) over each \( \partial D_i, i = 1 \ldots N \) and use the results of Lemmas 2.9 and 2.10 to find that, up to an error of \( O(\delta \omega^2 \ln \omega) + O(\omega^4 \ln \omega) \),

\[
B_{\delta}^{(i)}(\omega)[\phi] := \left( \int_{\partial D_i} \phi \right) \left( \omega^2 \ln \omega + \left( 1 + \frac{c_1}{b_1} - \ln v_b \right) - \frac{S_D[\phi]|_{\partial D_i}}{4b_1(\int_{\partial D} \phi)} \omega^2 \right)
- \frac{v_b^2}{4b_1|D_i|} \left[ \int_{\partial D_i} \phi + \frac{\ln(v/v_b)}{2\pi} \left( \int_{\partial D} \phi \right) \int_{\partial D_i} (S_D^{k_0})^{-1}[\chi_{\partial D}] \delta \right] = 0.
\]

When we substitute the expression (18) for \( \phi \) in (20) we find the system of equations, up to an error of order \( O(\delta \omega^2 \ln \omega) + O(\omega^4 \ln \omega) \),

\[
\begin{pmatrix}
B_{\delta}^{(1)}(\omega)[\phi_1] & B_{\delta}^{(1)}(\omega)[\phi_2] & \cdots & B_{\delta}^{(1)}(\omega)[\phi_N] \\
\vdots & \vdots & \ddots & \vdots \\
B_{\delta}^{(N)}(\omega)[\phi_1] & B_{\delta}^{(N)}(\omega)[\phi_2] & \cdots & B_{\delta}^{(N)}(\omega)[\phi_N]
\end{pmatrix}
\begin{pmatrix}
a_1 \\
\vdots \\
a_N
\end{pmatrix}
= 0.
\]

Remark 2.13. Thanks to the linearity of the operators \( B_{\delta}^{(i)} \), the solutions \( \omega(\delta) \) to (21) (as well as the associated eigenmodes) are independent of the choice of basis \( \{ \phi_1, \ldots, \phi_N \} \).
Figure 2: The resonant frequencies, plotted in the complex plane, of a system of 50 bundles arranged linearly with each being 1.05 times the size of the previous. The first resonance \( \omega_1 = 0.0002284 - 0.0000526i \) is omitted. We take \( \delta = 1/7000 \) in this simulation.

**Remark 2.14.** One can think of the step where we integrated (16) over each \( \partial D_i \), for \( i = 1, \ldots, N \), to give (20) as the point where the hybridisation (between the \( N \) resonators) was performed (see also e.g. [5]).

### 2.3 Numerical computations of resonant modes

In order to improve computational efficiency, we will assume from here onward that the cell bundles are circular. This means that we can use the so-called multipole expansion method, an explanation of which is provided in e.g. [6, Appendix C]. The method relies on the idea that functions in \( L^2(\partial D) \) are, on each circular \( \partial D_i \), 2\( \pi \)-periodic so we may approximate by the leading order terms of a Fourier series representation. We found that in most cases as few as seven terms was sufficient to give satisfactory results.

Using such an approach we can find, for each fixed \( \delta > 0 \), the \( N \) values of \( \omega \in \mathbb{C} \) such that there exists a nontrivial solution to (21). For the case where \( N = 50 \) the results are shown in Figure 2. We see that there is a range of frequencies where the (the real part of the) resonances occur most commonly. As \( N \) is increased, the resonances become increasingly dense in this region. In fact, with the current arrangement, this range of frequencies does not change as \( N \) increases. Instead, the region becomes increasingly densely filled.

It is also seen from Figure 2 that the imaginary parts of the resonances is smallest in the region where they are most dense. This means that these frequencies experience the least significant attenuation, suggesting that this range of frequencies is that which we might call “easily audible”.

The reason \( \omega_1 = 0.0002284 - 0.0000526i \) has been omitted from Figure 2 is due to its \( O(10^{-5}) \) imaginary part. This is not only inconvenient for plotting but also means that this resonant mode will suffer much greater attenuation and thus will be a less significant part of the motion over time.
Figure 3: The eigenmodes $u_1 \ldots, u_6$ for a system of six cell bundles arranged linearly with each being 1.05 times the size of the previous (smallest on the left). Each pair of plots corresponds to one of the six resonant frequencies. The upper plot shows a contour plot of the function $\Re u_n(x_1, x_2)$. The lower plot shows the cross section of this, taken along the line $x_2 = 0$ (i.e. through the centres of the bundles). The eigenmodes have been normalised such that $\int_D |u_n|^2 \, dx = 1$ for each $n = 1, \ldots, N$. 
It is also important to understand the eigenmodes $u_n$ associated with each resonant frequency $\omega_n$. The six resonant modes for the case of six cell bundles are shown in Figure 3. They take the form of increasingly oscillating patterns. In the lowest frequency eigenmode the cell bundles act as a monopole while the highest resonant frequency corresponds to a mode that oscillates between each adjacent bundle.

It is also notable that the solution is approximately constant on each bundle. This is because the solution, taking the form (9), is given by $S_D^k[\phi]$ at leading order which by Lemma 2.11 is constant for $\phi \in \ker(-\frac{1}{2}Id + K_D^*)$.

### 2.4 Signal processing

We wish to offer an explanation of how, given an incident wave $p^{in}(x,t)$, our system of coupled resonators is able to classify (and hence identify) the sound. The system of resonators $D$ is able to decompose the signal over its resonant modes. It is clear that the $N$ eigenmodes are linearly independent so we may define the relevant $N$-dimensional solution spaces.

**Definition 2.15.** We define the $N$-dimensional spaces $X$ and $Y$ as

\[
X := \text{span}\{u_1(x), \ldots, u_N(x)\},
\]

\[
Y := \text{span}\{u_1(x)e^{-i\omega_1 t}, \ldots, u_N(x)e^{-i\omega_N t}\},
\]

We will approximate the solution by a decomposition in the frequency domain. The fact that, for $n = 1, \ldots, N$, the Fourier transform of $e^{-i\omega_n t}$ for $t > 0$ is given by $i/(\omega - \omega_n)$ motivates us to employ the form

\[
u(x, \omega) \simeq \sum_{n=1}^{N} \frac{\alpha_n(\omega)i}{\omega - \omega_n} u_n(x),
\]

where $\alpha_1, \ldots, \alpha_N$ are complex-valued functions of a real variable.

It is important to understand whether knowing the value of the solution on each cell bundle (which is the information that a cochlea is able to capture) means that one can recover the weight functions $\alpha_1, \ldots, \alpha_N$ in (24).

**Remark 2.16.** The eigenmodes $u_1, \ldots, u_N$ are not orthogonal in $L^2(D)$.\(^\dagger\)

**Proposition 2.17.** Let $\{\omega_1, \ldots, \omega_N\}$ be the resonances of the system $D = D_1 \cup \ldots \cup D_N$ and denote by $u_1, \ldots, u_N$ the corresponding eigenmodes. Then the matrix $\gamma \in \mathbb{C}^{N \times N}$ defined by

\[
\gamma_{ij} := \int_D u_i(x)\overline{u_j(x)} \, dx \quad i, j = 1 \ldots N,
\]

is invertible.

\(^\dagger\)It turns out however that they are nearly orthogonal. For example, the normalised eigenmodes shown in Figure 3 satisfy $(u_n, u_m)_{L^2(D)} = O(10^{-3})$ for $n \neq m$. 

12
Proof. We can apply the Gram-Schmidt procedure to produce a basis \( \{ v_1, \ldots, v_N \} \) for \( X \) that is orthonormal with respect to \( (\cdot, \cdot)_{L^2(D)} \). This procedure produces a nonsingular lower triangular matrix \( P \in \mathbb{C}^{N \times N} \) such that \( (v_1, \ldots, v_N)^T = P(u_1, \ldots, u_N)^T \) (superscript \( T \) denotes the matrix transpose). If we define \( Q \in \mathbb{C}^{N \times N} \) as \( Q := P^{-1} \) then \( Q \) is also nonsingular and lower triangular.

We can then calculate that

\[
\begin{bmatrix}
  u_1 \\
  \vdots \\
  u_N 
\end{bmatrix}
\begin{bmatrix}
  v_1 \\
  \vdots \\
  v_N 
\end{bmatrix}
= Q
\begin{bmatrix}
  u_1 \\
  \vdots \\
  u_N 
\end{bmatrix}
\begin{bmatrix}
  v_1 \\
  \vdots \\
  v_N 
\end{bmatrix}
Q^T. 
\]

Integrating (26) componentwise gives that, for \( i, j = 1, \ldots, N \), it holds that

\[
\gamma_{ij} = [Q I_N Q^T]_{ij},
\]

and thus

\[
det(\gamma) = |det(Q)|^2 > 0. \tag{28}
\]

In order to find the weight functions \( \alpha_1, \ldots, \alpha_N \) in Equation (24) we must take the \( L^2(D) \)-product with \( u_n(x) \) for \( n = 1, \ldots, N \) and then invert \( \gamma \). This gives that

\[
\begin{bmatrix}
\frac{\alpha_1(\omega)}{\omega - \omega_1} \\
\vdots \\
\frac{\alpha_N(\omega)}{\omega - \omega_N}
\end{bmatrix}
= \gamma^{-1} \begin{bmatrix}
  (u(\cdot, \omega), u_1)_{L^2(D)} \\
  \vdots \\
  (u(\cdot, \omega), u_N)_{L^2(D)}
\end{bmatrix}. \tag{29}
\]

Consider extending the weight functions \( \alpha_1, \ldots, \alpha_N : \mathbb{R} \to \mathbb{C} \) to functions on all of \( \mathbb{C} \) such that they are constant along lines parallel to the imaginary axis (i.e. \( \alpha_n(\omega) := \alpha_n(\Re(\omega)) \) for \( \omega \in \mathbb{C}, n = 1, \ldots, N \)). Then, subject to the assumption that (the extended versions of) \( \alpha_1, \ldots, \alpha_N \) are analytic, we can recover from (24) a similar decomposition for \( p(x, t) \) using the Fourier inversion theorem

\[
p(x, t) \simeq \frac{1}{2\pi} \sum_{n=1}^N u_n(x) \int_{-\infty}^{\infty} \frac{\alpha_n(\omega) i e^{-i\omega t} d\omega}{\omega - \omega_n} = \sum_{n=1}^N u_n(x) \alpha_n(\omega_n) e^{-i\omega_n t}, \quad t > 0.
\]

Example 2.18. \( p^{in}(x, t) \) is a plane wave

We take as an example the case where \( p^{in}(x, t) \) is a pulse of a plane wave with frequency \( \omega_{in} \in \mathbb{R} \) travelling in the \( x_1 \) direction. This is given by

\[
p^{in}(x, t) = e^{i\omega_{in}(x_1/v - t)}, \quad 0 < t < 1.
\]
Figure 4: A system of six cell bundles filters a signal into the six resonant frequencies. We consider a system of six linearly arranged circular cell bundles that increase in size by a factor of $1.05$, which is subjected to an incoming plane wave with frequency $\omega_{in}$. The first plot shows how the norm of the solution $u(x, \omega)$ to (5) varies as a function of $\omega_{in}$. We then show how each coefficient $\alpha_1(\omega_1), \ldots, \alpha_N(\omega_N)$ in (30) varies. The six resonant frequencies of this system are $\omega_1 = 0.02752 - 0.000009i$, $\omega_2 = 0.08026 - 0.000009i$, $\omega_3 = 0.11659 - 0.000009i$, $\omega_4 = 0.014703 - 0.000004i$, $\omega_5 = 0.016976 - 0.000009i$, $\omega_6 = 0.019096 - 0.000004i$.

This has Fourier transform
\[ u^{in}(x, \omega) = 2e^{\frac{i}{2}(\omega - \omega_{in})}\text{sinc}(\omega - \omega_{in})e^{i\omega_{in}x_1/v}. \]

We can then compute $\alpha_1(\omega), \ldots, \alpha_N(\omega)$ as in (29).

In Figure 4 we show firstly how the $L^2(D)$-norm of the solution to the scattering problem (5) varies as a function of $\omega_{in}$. As is expected, the response is (locally) much greater when $\omega_{in}$ is close to $\Re(\omega_n)$ for some $n = 1, \ldots, N$.

In Figure 4 we also show how the weights $\alpha_1(\omega_1), \ldots, \alpha_N(\omega_N)$ in (30) vary as a function of $\omega_{in}$. Each constant is small except in a region of the associated resonant frequency when the corresponding eigenmode is excited most strongly. It should also be noted that $|\alpha_n(\omega_n)|$ decreases in $n$. If we considered higher order resonances the corresponding constants would be significantly smaller. This justifies our choice to approximate $p$ as an element of $Y$ in (30) (i.e. to only consider the $N$ subwavelength modes).

2.5 Travelling wave phenomenon

In trying to resolve the differences between the two main classes of cochlear model a crucial realisation is that our (resonance) model exhibits the travelling wave behaviour observed by Békésy. This is easy to see in models with graded arrays of uncoupled resonators, since a resonator’s response time will
increase with decreasing characteristic frequency [17, 11], but is also true of our hybridised model.

While it is true that acoustic waves enter the cochlea at the base and travel through the fluid to the apex, the travelling wave observed by Békésy moves much more slowly than this. The speed of sound in cochlea fluid is approximately $1500 \text{m s}^{-1}$ whereas the travelling wave is observed at speeds close to $10 \text{m s}^{-1}$ [11, 15]. This justifies the assumption that all the hair cells are excited simultaneously by an incoming signal. Under such an assumption, exciting an array initially at rest will produce the motion shown in Figure 5, from which the existence of a wave travelling from the small high-frequency resonators at the base of the cochlea to the larger low frequency resonators at the apex is clear.

It is important to note that the travelling wave observed in Figure 5 is merely the movement of the peak amplitude along the array of resonators. It is a consequence of the asymmetric eigenmodes growing from rest at different rates. This explains why experimentalists have not observed a reverse travelling wave moving back along the cochlea, as would be required by Békésy’s travelling wave model for energy conservation [11, 22].

It is clear from Figure 5 that the amplitude initially increases before quickly decreasing as the wave moves through the cochlea. This is consistent with experimental observations [17] and is to be expected in light of the $e^{-i\omega_n t}$ factors $(3(\omega_n) < 0)$ in (30). It is observed experimentally (in humans) that the travelling wave slows down as it moves through the cochlea [15]. This is also witnessed in Figure 5: the position of the wave moves relatively little between the third and fifth plots.
3 Concluding remarks

In this paper, we have computed leading order approximations to the resonant frequencies and associated eigenmodes for a system of coupled subwavelength oscillators that are graded in size. This model has the ability to decompose incoming signals into these resonant modes. It is a significant observation that the graded resonance model predicts the (widely observed) travelling wave behaviour, contributing to the unification of Helmholtz’ and Békésy’s models [11].

It has been demonstrated experimentally that sensitivity to different sound frequencies can be mapped as a function of location along the cochlea and that each hair cell bundle has a narrow frequency range which will cause it to produce a much greater electrical response [12, 13]. Our coupled model struggles to resolve this localised behaviour. Indeed, one needs to know the (approximately constant) value of \( u \) on every cell bundle in order to recover the constants \( \alpha_1(\omega_1), \ldots, \alpha_N(\omega_N) \) in (30).

On the other hand, it is also well known that the cochlea is an active organ [19, 20, 14, 21, 22]. In future work we will investigate how introducing appropriate forcing terms in (1) can produce the desired frequency selectivity by individual resonant elements.
