#### Abstract

We consider parabolic problems $\dot{u}+A u=f$ in $(0, T) \times \Omega, T<\infty$, where $\Omega \subset \mathbb{R}^{d}$ is a bounded domain and $A$ is a strongly elliptic, classical pseudodifferential operator of order $\rho \in[0,2]$ in $\tilde{H}^{\rho / 2}(\Omega)$. We use a $\theta$-scheme for time discretization and a Galerkin method with $N$ degrees of freedom for space discretization. The full Galerkin matrix for $A$ can be replaced with a sparse matrix using a wavelet basis, and the linear systems for each time step are solved approximatively with GMRES. We prove that the total cost of the algorithm for $M$ time steps is bounded by $O\left(M N(\log N)^{\beta}\right)$ operations and $O\left(N(\log N)^{\beta}\right)$ memory. We show that the algorithm gives optimal convergence rates (up to logarithmic terms) for the computed solution with respect to $L^{2}$ in time and the energy norm in space.

[^1]
## 1 Introduction

Fast algorithms such as wavelets, multipole or clustering methods for the numerical solution of elliptic integrodifferential equations

$$
\begin{equation*}
A[u](x)=\int_{\Omega} k(x, x-y) u(y) d y=f \quad x \in \Omega \tag{1.1}
\end{equation*}
$$

with kernel function $k(x, z)$ have been introduced and analyzed in recent years (see, e.g., $[3,4,7]$ ). In the present paper we investigate the numerical solution of a class of parabolic integrodifferential equations

$$
\begin{equation*}
u_{t}=A[u](x)+f \quad \text { in }(0, T) \times \Omega, \tag{1.2}
\end{equation*}
$$

with suitable initial and boundary conditions. Such equations arise as Kolmogorov forward equations for Lévy processes $X_{t}$ with infinitesimal generators $A[u]$. Brownian motion $B_{t}$ with diffusion $\sigma(x)$ and drift $r(x)$ is a particular Lévy process. The infinitesimal generator of $B_{t}$ in dimension $d=1$ is the second order elliptic differential operator

$$
\begin{equation*}
A_{B}[u](x)=-\frac{d}{d x}\left(\sigma(x) \frac{d u}{d x}(x)\right)+r(x) \frac{d u}{d x} \tag{1.3}
\end{equation*}
$$

and the Kolmogorov forward equation is the diffusion equation with drift. The decomposition theorem of P. Lévy states that the infinitesimal generator $A$ of any Lévy-process $X_{t}$ is the sum of a differential operator $A_{B}$ as in (1.3) which accounts for the diffusion part of $X_{t}$ and could possibly vanish and of a nonlocal operator $A_{L}$ of the form (1.1) which corresponds to the pure jump part of the process (see, e.g., $[2,12]$ ). The order $\rho$ of the infinitesimal generator $A$ of a Lévy-process always satisfies

$$
\begin{equation*}
0 \leq \rho \leq 2 . \tag{1.4}
\end{equation*}
$$

We emphasize that due to (1.4) the kernels $k(x, z)$ are not integrable near $z=0$ and that the integral in (1.1) has to be understood as finite part or principal value, i.e. in the sense of distributions [14]. Interpretations of the integral operators $A$ in the distribution sense can naturally be accounted for in Galerkin discretizations.

While the initial-boundary value problems (1.2) with (1.3) and constant $\sigma, r$ can be solved analytically for certain initial conditions, numerical solutions are required for nonconstant coefficients, general Lévy processes and free boundary problems arising with optimal stopping of $X_{t}$. In a numerical solution, $u(x, t)$ is approximated by Finite Differences or Finite Elements in $x$ with $N$ degrees of freedom, reducing (1.2) to a system of $N$ ordinary differential equations for the approximation $u_{N}$ which must be integrated in $t$ by a time-stepping scheme. We consider the $\theta$-scheme for time discretization which includes as special cases forward Euler $(\theta=0)$, backward Euler $(\theta=1)$, and Crank-Nicolson $\left(\theta=\frac{1}{2}\right)$. In general this leads to implicit methods where a linear system has to be solved for each time step. For the differential operator (1.3) in dimension $d=1$, the matrices to be inverted in each time-step are banded and can be factored in $O(N)$ operations. If the operator $A$ is nonlocal, however, standard Galerkin discretizations of $u$ with $N$ degrees of freedom entail dense stiffness matrices and hence at least $O\left(N^{2}\right)$ complexity per time step for the numerical solution of (1.2). We reduce this complexity by a wavelet-based matrix compression. The basic idea behind this compression is to represent the Galerkin approximation $u_{N}$ of (1.2) in a wavelet basis. Wavelet matrix compression exploits that the generators $A$ are often classical pseudodifferential operators which implies special properties of their Schwartz kernel function $k(x, z)$ such as

$$
\operatorname{sing} \operatorname{supp}(k(x, z)) \subset\{z=0\}
$$

and even analyticity of $k(x, z)$ off the origin $z=0$. Wavelet matrix compression requires only finite differentiability of $k(x, z)$ for $z \neq 0$ and allows the generation of an approximate stiffness matrix of the nonlocal operator $A$ in (1.1) in $O\left(N(\log N)^{a}\right)$ memory and operations where $a \geq 0$ is a small integer (see e.g. $[3,4,10,9,11,13]$ and the references there).

The analysis of the impact of this truncation error on stability and consistency of the $\theta$ time-stepping scheme for the nonlocal parabolic initial boundary value problems (1.1), (1.2) is the purpose of the present paper. A large body of literature on time-stepping for parabolic problems with Galerkin discretization is available, see [16]. However, our setting with integral operators and matrix compression causes consistency errors which don't fit readily into existing error estimates.

As it is well-known, the stability of explicit time-stepping schemes for Galerkin discretizations for parabolic problems (1.2), (1.4) requires a CFL condition which, as we will show, depends on the order $\rho$ of the operator $A$ and which takes the form

$$
\begin{equation*}
\Delta t \leq C(\Delta x)^{\rho}, \quad \rho \in[0,2] . \tag{1.5}
\end{equation*}
$$

For $\rho=2$, e.g. the heat equation, we recover the classical CFL condition which forces small time-steps $\Delta t$ in explicit schemes when the meshwidth $h=\Delta x$ of the space discretization is reduced. If, however, the order of $A$ is $\rho \leq 1$, condition (1.5) is of the type usually encountered in time-stepping for first order hyperbolic equations and explicit time-stepping schemes appear competitive.

Next, we present classes of spline wavelets and a matrix compression strategy which leads to sparse approximations for the stiffness matrix of $A$ with $O(N \log N)$ (rather than $O\left(N^{2}\right)$ for standard Galerkin schemes) nonvanishing entries. We prove that this compression preserves the asymptotic convergence rates of the full Galerkin scheme.

In the $\theta$-scheme, a linear system of equations at each implicit time-step must be solved. Since the compressed matrices are not banded and possibly nonsymmetric (due to the presence of a drift term or if $k(x, z)$ is asymmetric for $z \rightarrow \pm \infty)$, we propose inexact equation solution by GMRES iteration. Using wavelets, we precondition the compressed matrix in dependence on the discretization parameters and the order $\rho$ of $A$. We relate the GMRES stopping criterion to the discretization error of the scheme and prove that the resulting method converges still of optimal order in space and time while its complexity is essentially $O(N)$ memory and operations per (explicit or implicit) time-step. This is comparable to the complexity for the heat equation using backward Euler in time and banded matrices in space.

We emphasize that our analysis is applicable to general kernels $k(x, z)$, translation invariant or not, of any order $\rho \geq 0$. Therefore, the $\theta$-scheme with wavelet compression allows the numerical solution of the Kolmogorov equations (1.2) for a large class of Lévy processes with complexity comparable to standard finite differences for the heat equation in one dimension.

The outline of the paper is as follows: In Section 2 we present the class of parabolic problems and the class of spatial integro-differential operators $A$ admissible in our analysis. In Section 3, we discuss the fully discrete $\theta$-scheme. We describe wavelet Galerkin discretization of $A$ and give several examples of wavelets. Section 4 is devoted to the stability analysis of the $\theta$-scheme with compression in the "explicit" case $0 \leq \theta<\frac{1}{2}$ as well as in the implicit case $\theta>\frac{1}{2}$. In Section 5 , we prove our convergence estimates with particular attention to the error due to wavelet compression of the stiffness matrix A of $A$. Section 6 is devoted to the proof of the complexity estimates, the matrix preconditioning in the implicit time-stepping schemes and the analysis of the error in the presence of incomplete GMRES iterations. Throughout, $C$ will denote a generic positive constant independent of the discretization parameters taking different values in different places. If the value of $C$ is relevant, we write also $C_{i}$.

## 2 Problem Formulation

In the time interval $J=(0, T)$ with $T>0$, we consider parabolic evolution problems of the form

$$
\begin{align*}
u^{\prime}(t)+A u(t) & =g(t), t \in J  \tag{2.1}\\
u(0) & =u_{0} \tag{2.2}
\end{align*}
$$

where $A$ is a possibly nonlocal operator of order $\rho>0$.
For a variational formulation of this problem we introduce Sobolev spaces. Let $\Omega \subset \mathbb{R}^{d}$ be a bounded domain with Lipschitz boundary $\Gamma=\partial \Omega$. We denote by $H=L^{2}(\Omega)$ the usual square integrable functions with inner product (.,.) and by $H^{s}(\Omega), s \geq 0$, the corresponding Sobolev spaces (see, e.g., [1]). Further, for $s \geq 0$, we define the space

$$
\begin{equation*}
\tilde{H}^{s}(\Omega)=\left\{\left.u\right|_{\Omega}\left|u \in H^{s}\left(\mathbb{R}^{d}\right), u\right|_{\mathbb{R}^{d} \backslash \Omega}=0\right\} \tag{2.3}
\end{equation*}
$$

If $s+1 / 2 \notin \mathbb{N}$, then $\tilde{H}^{s}(\Omega)$ coincides with $H_{0}^{s}(\Omega)$, the closure of $C_{0}^{\infty}(\Omega)$ with respect to the norm in $H^{s}(\Omega)$. We identify $L^{2}(\Omega)$ with its dual and denote by

$$
\begin{equation*}
V=\tilde{H}^{\rho / 2}(\Omega) \tag{2.4}
\end{equation*}
$$

Then $V \stackrel{d}{\hookrightarrow} L^{2}(\Omega)$ with dense injection and $V^{*}$, the dual of $V$, satisfies

$$
\begin{equation*}
V \stackrel{d}{\hookrightarrow} L^{2}(\Omega) \stackrel{d}{\hookrightarrow} V^{*} . \tag{2.5}
\end{equation*}
$$

We assume that $A \in \mathcal{L}\left(V, V^{*}\right)$. By $(\cdot, \cdot)_{V^{*} \times V}$ we denote the extension of (., .) as duality pairing in $V^{*} \times V$ and by $\|\cdot\|,\|\cdot\|_{V},\|\cdot\|_{V^{*}}$ the norms in $L^{2}(\Omega), V, V^{*}$, resp. We associate with $A$ the bilinear form $a(\cdot, \cdot): V \times V \rightarrow \mathbb{C}$ via

$$
\begin{equation*}
a(u, v):=(A u, v)_{V^{*} \times V}, u, v \in V, A u \in V^{*} \tag{2.6}
\end{equation*}
$$

Then the form $a(\cdot, \cdot)$ is continuous

$$
\begin{equation*}
\forall u, v \in V: \quad|a(u, v)| \leq \alpha\|u\|_{V}\|v\|_{V} \tag{2.7}
\end{equation*}
$$

and we assume that it is coercive in the sense that

$$
\begin{equation*}
\forall u \in V: \quad a(u, u) \geq \beta\|u\|_{V}^{2}, \tag{2.8}
\end{equation*}
$$

for some $0<\beta \leq \alpha<\infty$. Then $A \in \mathcal{L}\left(V, V^{*}\right)$ is an isomorphism and $\|A\|_{\mathcal{L}\left(V, V^{*}\right)} \leq \alpha$, $\left\|A^{-1}\right\|_{\mathcal{L}\left(V^{*}, V\right)} \leq \frac{1}{\beta}$. The time derivative $u^{\prime}(t)$ in (2.1) is understood in the weak sense, i.e. for $u \in L^{2}(J, V)$ we have $u^{\prime} \in L^{2}\left(J, V^{*}\right)$ defined by

$$
\begin{equation*}
\int_{J}\left(u^{\prime}(t), v\right)_{V^{*} \times V} \varphi(t) d t=-\int_{J}(u(t), v) \varphi^{\prime}(t) d t \tag{2.9}
\end{equation*}
$$

for every $v \in V, \varphi \in C_{0}^{\infty}(J)$. The weak form of (2.1), (2.2) reads:
given

$$
\begin{equation*}
u_{0} \in H, g \in L^{2}(J ; H) \tag{2.10}
\end{equation*}
$$

find $u \in L^{2}(J, V) \cap H^{1}\left(J, V^{*}\right)$ such that $u(0)=u_{0}$ and, for every $v \in V, \varphi \in C_{0}^{\infty}(J)$,

$$
\begin{equation*}
-\int_{J}(u(t), v) \varphi^{\prime}(t) d t+\int_{J} a(u, v) \varphi(t) d t=\int_{J}(g(t), v)_{V^{*} \times V} \varphi(t) d t \tag{2.11}
\end{equation*}
$$

Note that the initial condition is well defined since

$$
\begin{equation*}
L^{2}(J, V) \cap H^{1}\left(J, V^{*}\right) \subset C^{0}([0, T] ; H) \tag{2.12}
\end{equation*}
$$

Under the assumption (2.10), problem (2.11) has a unique weak solution $u(t)$ and there holds the a-priori estimate [8]

$$
\begin{equation*}
\|u\|_{C(\bar{J} ; H)}+\|u\|_{L^{2}(J ; V)}+\left\|u^{\prime}\right\|_{L^{2}\left(J ; V^{*}\right)} \leq C\left(\|g\|_{L^{2}(J ; H)}+\left\|u_{0}\right\|_{H}\right) \tag{2.13}
\end{equation*}
$$

## Remark 2.1.

i) We do not assume $A$ to be self-adjoint. The form $a(\cdot, \cdot)$ need not be symmetric.
ii) Properties (2.7) and (2.8) allow to define on $V$ an equivalent norm by

$$
\begin{equation*}
\|u\|_{a}:=(a(u, u))^{1 / 2} \sim\|u\|_{V} \tag{2.14}
\end{equation*}
$$

to which we shall refer below as "energy-norm".
iii) Testing (2.1) with $u(t)$ in the $(\cdot, \cdot)$ inner product, we find with $(2.6)$ that for almost every $t \in(0, T)$

$$
\left(u, u^{\prime}\right)+a(u, u)=(u, g),
$$

and integrating from $t=0$ to $t=T$, we find

$$
\begin{aligned}
& \frac{1}{2}\|u(T)\|^{2}-\frac{1}{2}\|u(0)\|^{2}+\int_{0}^{T} a(u(t), u(t)) d t=\int_{0}^{T}(u, g) d t \\
& \leq \int_{0}^{T}\|u(t)\|_{a} \sup _{v \in V} \frac{(v, g)}{\|v\|_{a}} d t \leq \frac{1}{2} \int_{0}^{T}\|u(t)\|_{a}^{2} d t+\frac{1}{2} \int_{0}^{T}\|g(t)\|_{V^{*}}^{2} d t
\end{aligned}
$$

which implies the a-priori estimate

$$
\begin{equation*}
\|u(T)\|^{2}+\int_{0}^{T}\|u(t)\|_{a}^{2} d t \leq\|u(0)\|^{2}+\int_{0}^{T}\|g(t)\|_{V^{*}}^{2} d t \tag{2.15}
\end{equation*}
$$

where we have set, for any $g \in V^{*}$,

$$
\|g\|_{V^{*}}=\sup _{v \in V} \frac{(g, v)}{\|v\|_{a}}
$$

Some examples follow.

Example 2.2. (Diffusion problem) Here $\rho=2$ and

$$
A=-\nabla \cdot \mathbf{D}(x) \nabla, \quad V=H_{0}^{1}(\Omega) \stackrel{d}{\hookrightarrow} L^{2}(\Omega)=H, \quad a(u, v)=\int_{\Omega} \nabla v \cdot \mathbf{D}(x) \nabla u d x
$$

where $\quad \mathbf{D} \in L^{\infty}(\Omega)^{d \times d}$ satisfies for some $\gamma>0$

$$
\xi^{T} \mathbf{D}(x) \xi \geq \gamma|\xi|^{2} \quad \forall \underline{\xi} \in \mathbb{R}^{n}, \text { a.e. } x \in \Omega
$$

Then (2.1), (2.2) is the Dirichlet problem for the heat equation in $\Omega \times(0, T)$.
In this example, the operators $A$ are differential operators and in particular local. The nonlocal operators $A$ of interest to us are classical pseudodifferential operators.
Example 2.3. For $0 \leq \rho \in \mathbb{R}, \Omega \subset \mathbb{R}^{d}$ open, bounded and Lipschitz, we consider classical pseudo-differential operators of order $\rho \in[0,2]$ in $\Omega$, i.e. $A \in \Psi^{\rho}(\Omega)$ which acts from $V \rightarrow$ $V^{*}$ where $V=\widetilde{H}^{\frac{\rho}{2}}(\Omega)$. By the Schwartz kernel theorem (see, e.g. [14]), $A \in \Psi^{\rho}(\Omega)$ has a representation in terms of a distributional kernel

$$
\begin{equation*}
k(x, x-y) \in \mathcal{D}^{\prime}(\Omega \times \Omega) \tag{2.16}
\end{equation*}
$$

with associated bilinear form

$$
\begin{equation*}
a(u, v)=(A u, v)_{V^{*} \times V}=\langle k(x, x-y), v(x) \otimes u(y)\rangle \tag{2.17}
\end{equation*}
$$

Moreover, the kernel $k(x, x-y) \in C^{\infty}(\Omega \times \Omega \backslash\{x=y\})$ satisfies the so-called CalderónZygmund estimates: $\forall \alpha, \beta \in \mathbb{N}_{0}^{n}, \forall(x, y) \in \Omega \times \Omega \backslash\{x=y\}$ :

$$
\begin{equation*}
\left|\partial_{x}^{\alpha} \partial_{y}^{\beta} k(x, x-y)\right| \leq C(\alpha, \beta)|x-y|^{-(d+\rho+|\alpha|+|\beta|)} \tag{2.18}
\end{equation*}
$$

A particular example for a nonlocal operator of order $\rho=1$ is given by $\Omega=(-1 / 2,1 / 2) \subset \mathbb{R}$ and, for $u \in V=\widetilde{H}^{1 / 2}(\Omega)$ :

$$
\begin{equation*}
(A u)(x)=- \text { p.f. } \int_{\Omega} \frac{u(y)}{|x-y|^{2}} d y \tag{2.19}
\end{equation*}
$$

where the integral is to be understood in the finite-part sense (see, e.g. [14]). For the bilinear form $a(u, v)$ corresponding to the hypersingular operator $W$ in (2.19) integration by parts yields the representation

$$
\begin{equation*}
\forall u, v \in \widetilde{H}^{1 / 2}(\Omega): a(u, v)=-\int_{\Omega} v^{\prime}(x) \int_{\Omega} \log (x-y) u^{\prime}(y) d y d x \tag{2.20}
\end{equation*}
$$

and one can show that there are $\beta, \gamma>0$ with

$$
\begin{equation*}
\forall u \in \widetilde{H}^{1 / 2}(\Omega): a(u, u) \geq \beta\|u\|_{\widetilde{H}^{1 / 2}(\Omega)}^{2} \tag{2.21}
\end{equation*}
$$

Remark 2.4. In the setting (2.17), we often do not have the coercivity (2.8), but rather a (weaker) Garding inequality: there is $\gamma \geq 0$ such that

$$
\begin{equation*}
\forall u \in V: a(u, u)+\gamma\|u\|^{2} \geq \beta\|u\|_{V}^{2} \tag{2.22}
\end{equation*}
$$

This case can be reduced to (2.8) by the substitution $w=\exp (-\gamma t) u$, since then (2.1) implies that $w$ solves the problem

$$
w^{\prime}+(A+\gamma I) w=\exp (-\gamma t) g \text { in }(0, T)
$$

and the operator $A+\gamma I$ is, by (2.19), once again coercive.

## 3 Discretization

We discretize (2.1) in time using the so-called $\theta$-scheme and in space by a finite element method. We describe wavelet finite element bases and the compression of the stiffness matrix.

### 3.1 Space Discretization

To discretize the parabolic problem (2.11) in space, we use an elliptic projection onto a family $\left\{V_{h}\right\}_{h} \subset V$ of finite dimensional subspaces of $V$, based on piecewise polynomials of degree $p \geq 0$ on a quasiuniform family of triangulations $\left\{\mathcal{T}_{h}\right\}_{h}$ of $\Omega$.

The semidiscrete problem reads: given $u_{0} \in H, g \in L^{2}(J, H)$, first choose an approximation $u_{0, h} \in V_{h}$ for the initial data $u_{0}$. Then find $u_{h} \in H^{1}\left(J, V_{h}\right)$ such that

$$
\begin{equation*}
u_{h}(0)=u_{0, h} \tag{3.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{d}{d t}\left(u_{h}, v_{h}\right)+a\left(u_{h}, v_{h}\right)=\left(g(t), v_{h}\right) \quad \forall v_{h} \in V_{h} . \tag{3.2}
\end{equation*}
$$

The approximation of the intial data could be chosen as $u_{0, h}=P_{h} u_{0}$ with some projector $P_{h}: L^{2} \rightarrow V_{h}$, or as an interpolation of $u_{0}$.

The semidiscrete problem (3.1), (3.2) is an initial value problem for $N=\operatorname{dim} V_{h}$ ordinary differential equations

$$
\mathbf{K} \frac{d}{d t} \underline{u}+\mathbf{A} \underline{u}=\underline{g}(t), \quad \underline{u}(0)=\underline{u}_{0}
$$

where $\underline{u}(t)$ denotes coeffcient vector of $u_{h}(t)$ with respect to some basis of $V_{h}$. Likewise $\underline{u}_{0}$ denotes the coefficient vector of $\underline{u}_{0}$ and $\mathbf{K}, \mathbf{A}$ denote the mass- and stiffness matrix, respectively, with respect to the basis of $V_{h}$.

In the ensuing error analysis, we need to consider functions in $V$ which have additional regularity and introduce for this purpose the spaces $\mathcal{H}^{s}(\Omega)$ which are defined as

$$
\mathcal{H}^{s}(\Omega)=\left\{\begin{array}{c}
V=\tilde{H}^{\rho / 2}(\Omega) \quad \text { for } s=\rho / 2, \\
V \cap H^{s}(\Omega) \quad \text { for } s>\rho / 2
\end{array}\right.
$$

We assume the approximation property: for all $u \in \mathcal{H}^{t}$ with $t \geq \rho / 2$ there exists a $u_{h} \in V_{h}$ such that for $0 \leq s \leq \frac{\rho}{2}$ and $\rho / 2 \leq t \leq p+1$

$$
\begin{equation*}
\left\|u-u_{h}\right\|_{\tilde{H}^{s}(\Omega)} \leq c h^{t-s}\|u\|_{\mathcal{H}^{t}(\Omega)} \tag{3.3}
\end{equation*}
$$

In section 3.4 below we will use a wavelet basis to define a projection $P_{h}: V \rightarrow V_{h}$ such that $u_{h}=P_{h} u$ satisfies (3.3).

We shall also need the inverse property: there is $c>0$ independent of $h$ such that

$$
\begin{equation*}
\forall u_{h} \in V_{h} \quad\left\|u_{h}\right\|_{\tilde{H}^{s}(\Omega)} \leq c h^{-s}\left\|u_{h}\right\|_{L^{2}(\Omega)}, \quad 0 \leq s \leq \rho / 2 \tag{3.4}
\end{equation*}
$$

### 3.2 Time discretization using the $\theta$-scheme

For $T<\infty$ and $M \in \mathbb{N}$, define the time step

$$
k=T / M
$$

and $t^{m}=m k, m=0, \ldots, M$. The fully discrete $\theta$-scheme reads as follows: given $u_{0} \in H$, find $u_{h}^{m} \in V_{h}$ satisfying

$$
\begin{equation*}
u_{h}^{0}=u_{0 . h}, \tag{3.5}
\end{equation*}
$$

and, for $m=0,1, \ldots, M-1$, find $u_{h}^{m+1} \in V$ such that for all $v_{h} \in V_{h}$

$$
\begin{equation*}
\left(\frac{u_{h}^{m+1}-u_{h}^{m}}{k}, v_{h}\right)+a\left(u_{h}^{m+\theta}, v_{h}\right)=\left(g\left(t^{m+\theta}\right), v_{h}\right) \tag{3.6}
\end{equation*}
$$

holds. Here $u_{h}^{m+\theta}:=\theta u_{h}^{m+1}+(1-\theta) u_{h}^{m}$ and $t^{m+\theta}=\theta t^{m+1}+(1-\theta) t^{m}=(m+\theta) k$. In matrix form, (3.6) reads

$$
\left(k^{-1} \mathbf{K}+\theta \mathbf{A}\right) \underline{u}^{m+1}=k^{-1} \mathbf{K} \underline{u}^{m}-(1-\theta) \mathbf{A} \underline{u}^{m}+\underline{g}^{m+\theta}, \quad m=0,1, \ldots, M-1 .
$$

where $\underline{u}^{m}$ is the coefficient vector of $u_{h}^{m}$ with respect to a basis of $V_{h}$.
Remark 3.1. Even for the forward Euler method (i.e. for $\theta=0$ ), we have to solve at each time step a linear system with the mass matrix. However, for $0 \leq \rho<1$ the spaces $H^{\rho / 2}(\Omega)$ and $\tilde{H}^{\rho / 2}(\Omega)$ are isomorphic and we can use discontinuous multiwavelets to obtain a diagonal mass matrix. In this case, each time step requires only one matrix-vector product with the matrix $\mathbf{A}$.

### 3.3 Perturbation

Previous analyses of the $\theta$-scheme (3.5) assumed that the form $a(\cdot, \cdot): V_{h} \times V_{h} \rightarrow \mathbb{R}$ can be evaluated exactly, i.e. that the corresponding stiffness matrix $\mathbf{A}$ is available. This is not the case if we compress $\mathbf{A}$, resulting in a perturbed matrix $\tilde{\mathbf{A}}$. With $\tilde{\mathbf{A}}$ we associate the form $\tilde{a}(\cdot, \cdot)$ (other perturbations e.g. due to numerical integration or domain approximation by isoparametric elements in the context of Example 2.2 can be treated in the same way). Using $\tilde{a}(\cdot, \cdot)$ in place of $a(\cdot, \cdot)$ in (3.6) gives perturbed $\theta$-schemes

$$
\begin{gather*}
\widetilde{u}_{h}^{0}=u_{0, h},  \tag{3.7a}\\
\left(\frac{\widetilde{u}_{h}^{m+1}-\widetilde{u}_{h}^{m}}{k}, v_{h}\right)+\widetilde{a}\left(\widetilde{u}_{h}^{m+\theta}, v_{h}\right)=\left(g\left(t^{m+\theta}\right), v_{h}\right) \tag{3.7b}
\end{gather*}
$$

for $m=0,1,2, \ldots, M-1$ and every $v_{h} \in V_{h}$, where again $\widetilde{u}_{h}^{m+\theta}:=\theta \widetilde{u}_{h}^{m+1}+(1-\theta) \widetilde{u}_{h}^{m}$. In matrix form, (3.7b) reads

$$
\left(k^{-1} \mathbf{K}+\theta \tilde{\mathbf{A}}\right) \tilde{\tilde{u}}^{m+1}=k^{-1} \mathbf{K} \underline{\tilde{u}}^{m}-(1-\theta) \tilde{\mathbf{A}} \underline{\tilde{u}}^{m}+\underline{g}^{m+\theta}, \quad m=0,1, \ldots, M-1
$$

where $\underline{\tilde{u}}^{m}$ is the coefficient vector of $\tilde{u}_{h}^{m}$ with respect to a basis of $V_{h}$.
We shall assume for $\widetilde{a}(\cdot, \cdot)$ the following consistency conditions: there is $\delta<1$ independent of $h$ such that

$$
\begin{equation*}
\left|a\left(u_{h}, v_{h}\right)-\widetilde{a}\left(u_{h}, v_{h}\right)\right| \leq \delta\left\|u_{h}\right\|_{a}\left\|v_{h}\right\|_{a} \quad \forall u_{h}, v_{h} \in V_{h} \tag{3.8}
\end{equation*}
$$

and there is $C>0$ independent of $h$ such that

$$
\begin{equation*}
\left|a\left(P_{h} u, v_{h}\right)-\widetilde{a}\left(P_{h} u, v_{h}\right)\right| \leq C h^{p+1-\rho / 2}|\log h|^{\nu}\|u\|_{\mathcal{H}^{p+1}(\Omega)}\left\|v_{h}\right\|_{\tilde{H}^{\rho / 2}(\Omega)} \quad \forall u \in \mathcal{H}^{p+1}(\Omega), v_{h} \in V_{h} \tag{3.9}
\end{equation*}
$$

with some $\nu \geq 0$.
Condition (3.8) shows that on $V_{h} \times V_{h}$ the form $\widetilde{a}(\cdot, \cdot)$ is equivalent to $a(\cdot, \cdot)$ in the following sense:

Proposition 3.2. For $\delta<1$ in (3.8), we have for some constants $0<\widetilde{\beta} \leq \widetilde{\alpha}<\infty$ independent of $h$

$$
\begin{equation*}
\forall u_{h}, v_{h} \in V_{h}:\left|\widetilde{a}\left(u_{h}, v_{h}\right)\right| \leq \widetilde{\alpha}\left\|u_{h}\right\|_{a}\left\|v_{h}\right\|_{a} \tag{3.10}
\end{equation*}
$$

and

$$
\begin{equation*}
\forall u_{h} \in V_{h}:\left|\widetilde{a}\left(u_{h}, u_{h}\right)\right| \geq \widetilde{\beta}\left\|u_{h}\right\|_{a}^{2} . \tag{3.11}
\end{equation*}
$$

Proof. Consider (3.11). We have for $u_{h} \in V_{h}$ :

$$
\left|\tilde{a}\left(u_{h}, u_{h}\right)\right| \geq\left|a\left(u_{h}, u_{h}\right)\right|-\left|a\left(u_{h}, u_{h}\right)-\tilde{a}\left(u_{h}, u_{h}\right)\right|=\left\|u_{h}\right\|_{a}^{2}-\left|a\left(u_{h}, u_{h}\right)-\tilde{a}\left(u_{h}, u_{h}\right)\right|
$$

and, using the definition of $\|\cdot\|_{a}$ and the consistency condition (3.8), we get (3.11) with $\tilde{\beta}=1-\delta$. The continuity (3.10) is proved in the same way.

### 3.4 Wavelet Compression

In the context of Example 2.3, perturbed bilinear forms $\widetilde{a}$ are obtained by various matrix compression techniques which reduce the dense matrices A to sparse ones which can be manipulated in linear complexity. We illustrate this by the wavelet compression of operators of order $0 \leq \rho \leq 2$ in dimensions $d=1,2$; we only present here the main principles - for details and proofs, see $[9,13,4]$. All results carry over to dimensions $d>2$ if a suitable wavelet basis is used.

### 3.4.1 Subspaces $V_{h}$

For $d=1$ the domain $\Omega$ is an interval. For $d=2$ we assume that $\Omega$ is a polygon. Let $T_{0}$ be a fixed coarse triangulation of the domain. We then define the triangulation $T_{l}$ for $l>0$ by bisection of each interval in $T_{l-1}$ for $d=1$, or by subdivision of a triangle in $T_{l-1}$ in four congruent subtriangles for $d=2$. We assume that the triangulation $\left\{\mathcal{T}_{h}\right\}$ is obtained in this way as $T_{L}$, for some $L>0$ so that $h=C 2^{-L}$.

For $0 \leq \rho<1$ we define $V_{h}$ as the space of piecewise polynomials of total degree $p \geq 0$ (without any continuity restriction) on the triangulation $T_{L}$.

For $1 \leq \rho \leq 2$ the space $V_{h}$ is defined as the space of continuous piecewise polynomials of degree $p \geq 1$ on the triangulation with zero values on the boundary $\partial \Omega$.

In the same way we define the spaces $V^{l}$ corresponding to the triangulation $T_{l}$, so that we have

$$
V^{0} \subset V^{1} \subset \cdots \subset V^{L}=V_{h} .
$$

Let $N^{l}=\operatorname{dim} V^{l}$ and $M^{l}:=N^{l}-N^{l-1}$ so that $N=\operatorname{dim} V_{h}=N^{L}=C 2^{L}$.

### 3.4.2 Wavelet basis

By choosing a suitable basis for $V_{h}$ we will be able to represent the bilinear form $a(\cdot, \cdot)$ as a matrix where most elements are small and can be neglected, yielding the approximate bilinear form $\tilde{a}(\cdot, \cdot)$. The basis will also allow optimal preconditioning. We will use so-called biorthogonal wavelets (note that the dual wavelets described below will not be used in the computation).

We will use a hierarchical basis of functions $\psi_{j}^{l}$ with $j=1, \ldots, M^{l}$ and $l=0,1, \ldots$ with the following properties: We have $\operatorname{span}\left\{\psi_{j}^{l} \mid 0 \leq l \leq L, 1 \leq j \leq M^{l}\right\}=V^{l}$.

The function $\psi_{j}^{l}$ has support $S_{j}^{l}:=\operatorname{supp} \psi_{j}^{l}$ of diameter bounded by $C 2^{-l}$.
Wavelets $\psi_{j}^{l}$ with $\bar{S}_{j}^{l} \cap \partial \Omega=\emptyset$ have vanishing moments up to order $p$, i.e., $\left(\psi_{j}^{l}, q\right)=0$ for all polynomials $q$ of total degree $p$ or less.

The functions $\psi_{j}^{l}$ for $l \geq l_{0}$ are obtained by scaling and translation of the functions $\psi_{j}^{l_{0}}$.
A function $v \in V_{h}$ has the representation

$$
v=\sum_{l=0}^{L} \sum_{j=1}^{M^{l}} v_{j}^{l} \psi_{j}^{l}
$$

with $v_{j}^{l}=\left(v, \tilde{\psi}_{j}^{l}\right)$ where $\tilde{\psi}_{j}^{l}$ are the so-called dual wavelets.
For $v \in V$ one obtains an infinite series

$$
v=\sum_{l=0}^{\infty} \sum_{j=1}^{M^{l}} v_{j}^{l} \psi_{j}^{l}
$$

with $v_{j}^{l}=\left(v, \tilde{\psi}_{j}^{l}\right)$ which converges in $\tilde{H}^{s}$ for $0 \leq s \leq \rho / 2$.
There holds the norm equivalence

$$
\begin{equation*}
c_{1}\|v\|_{\tilde{H}^{s}(\Omega)}^{2} \leq \sum_{l=0}^{\infty} \sum_{j=1}^{M^{l}}\left|v_{j}^{l}\right|^{2} 2^{2 l s} \leq c_{2}\|v\|_{\tilde{H}^{s}(\Omega)}^{2} \tag{3.12}
\end{equation*}
$$

for $0 \leq s \leq \rho / 2$ and for $\rho / 2<s \leq p+1$ we have the one-sided bounds

$$
\sum_{l=0}^{L} \sum_{j=1}^{M^{l}}\left|v_{j}^{l}\right|^{2} 2^{2 l s} \leq c_{3} L^{\nu}\|v\|_{\mathcal{H}^{s}(\Omega)}^{2}
$$

where $c_{i}>0$ are independent of $L, \nu=0$ if $s<p+1$ and $\nu=1$ if $s=p+1$.
For $v \in V$ we can define a projection $P_{h}: V \rightarrow V_{h}$ by truncating the wavelet expansion:

$$
\begin{equation*}
P_{h} v:=\sum_{l=0}^{L} \sum_{j=1}^{M^{l}} v_{j}^{l} \psi_{j}^{l} \tag{3.13}
\end{equation*}
$$

This projection satisfies the approximation property (3.3).

### 3.4.3 Examples for wavelets

In the case $0 \leq \rho<1$ a multiwavelet basis as in [11] can be used: Let $\left\{p_{k}\right\}$ be a basis for polynomials of total degree $p$ or less. Then the functions $\psi_{j}^{0}$ are the functions which are on one element equal to a function $p_{k}$, and zero elsewhere. For $l>1$ we choose for $\psi_{j}^{l}$ functions in $V^{l}$ which are nonzero on one element of $T_{l-1}$, and which are orthogonal on all polynomials of total degree $p$ or less.

In all cases $0 \leq \rho \leq 2$ so-called prewavelets can be used: These are functions in $V^{l}$ with small support which are orthogonal on $V^{l-1}$.

Another possiblity are so-called biorthogonal wavelets which need not be orthogonal on $V^{l-1}$. For piecewise linears the functions $\psi_{j}^{l}$ in the interior of the interval have values $0, \ldots, 0,-1,2,-1,0, \ldots, 0$. In the case of Neumann boundary conditions the wavelet at the left boundary has values $-2,2,1,0, \ldots, 0$; in the case of Dirichlet conditions the values are $0,2,-1,0, \ldots, 0$ (and similarly at the right boundary). Note that the boundary wavelets have fewer vanishing moments in general.

In dimension $d=2$ the construction of piecewise linear prewavelets on arbitrary polygons is described e.g. in $[5,15]$.

### 3.4.4 Matrix compression

The bilinear form $a$ on $V_{h} \times V_{h}$ corresponds to a matrix $\mathbf{A}$ with elements $A_{(l, j),\left(l^{\prime}, j^{\prime}\right)}=a\left(\psi_{j}^{l}, \psi_{j^{\prime}}^{l^{\prime}}\right)$.
We assumed that the kernel of the operator satisfies the estimates (2.18). This implies a decay of the matrix elements with increasing distance of their supports.

We define the compressed matrix $\tilde{\mathbf{A}}$ and the corresponding bilinear form $\tilde{a}$ by replacing certain small matrix elements in $\mathbf{A}$ with zero:

$$
\tilde{A}_{(j, l),\left(j^{\prime}, l^{\prime}\right)}:= \begin{cases}A_{(j, l),\left(j^{\prime}, l^{\prime}\right)} & \text { if } \operatorname{dist}\left(S_{j}^{l}, S_{j^{\prime}}^{l^{\prime}}\right) \leq \delta_{l, l^{\prime}} \text { or } S_{j}^{l} \cap \partial \Omega \neq \emptyset  \tag{3.14}\\ 0 & \text { otherwise }\end{cases}
$$

Here the truncation parameters $\delta_{l, l^{\prime}}$ are given by

$$
\begin{equation*}
\delta_{l, l^{\prime}}:=c \max \left\{2^{-L+\hat{\alpha}\left(2 L-l-l^{\prime}\right)}, 2^{-l}, 2^{-l^{\prime}}\right\} \tag{3.15}
\end{equation*}
$$

with some parameters $c>0$ and $\hat{\alpha}>0$. The consistency conditions (3.8), (3.9) can be satisfied (see e.g. $[9,10,11,13]$ ):

Proposition 3.3. If $c$ in (3.15) is chosen sufficiently large then for all $L>0$ condition (3.8) holds. If additionally

$$
\begin{equation*}
\hat{\alpha} \geq \frac{2 p+2}{2 p+2+\rho} \tag{3.16}
\end{equation*}
$$

holds then condition (3.9) holds with $\nu=\frac{3}{2}$ if equality holds in (3.16), and $\nu=\frac{1}{2}$ otherwise.
The matrix compression (3.14) reduces the number of nonzero elements from $N^{2}$ to $N$ times a logarithmic term $[9,10,11,13]$ :
Proposition 3.4. The compressed matrix $\tilde{\mathbf{A}}$ has $O(N \log N)$ nonzero elements if $\hat{\alpha}<1$, and $O\left(N(\log N)^{2}\right)$ nonzero elements if $\hat{\alpha}=1$.

In particular, for operators of order $\rho>0$ we can choose $\hat{\alpha}$ such that $\nu=\frac{1}{2}$ in (3.9) and the number of nonzero elements in $\tilde{\mathbf{A}}$ is $O(N \log N)$. In the case of order $\rho=0$ we have to choose $\hat{\alpha}=1$ implying $\nu=\frac{3}{2}$ in (3.9) and the number of nonzero elements in $\tilde{\mathbf{A}}$ is $O\left(N(\log N)^{2}\right)$.

## $4 \quad$ Stability

The stability of the $\theta$-scheme is well-known in the context of Example 2.2, i.e., if the spatial operator is elliptic and of second order. We investigate here general operators $A$ of order $\rho \geq 0$ that are elliptic in the sense that $(2.7),(2.8)$ hold in $V=\widetilde{H}^{\rho / 2}(\Omega)$. We prove an $L^{2}(J, V)$ stability estimate for the approximate solutions obtained from the $\theta$-scheme with wavelet-compressed space operator.

In the analysis, we will use for $f \in V_{h}^{*}$ the following notation:

$$
\begin{equation*}
\|f\|_{*}:=\sup _{v_{h} \in V_{h}} \frac{\left(f, v_{h}\right)}{\left\|v_{h}\right\|_{a}} \tag{4.1}
\end{equation*}
$$

We will also need $\lambda_{A}$ defined by

$$
\lambda_{A}:=\sup _{v_{h} \in V_{h}} \frac{\left\|v_{h}\right\|^{2}}{\left\|v_{h}\right\|_{*}^{2}}
$$

We first address the stability of the $\theta$-scheme with exact bilinear form $a(\cdot, \cdot)$. In the case $\frac{1}{2} \leq \theta \leq 1$, the $\theta$-scheme is stable for any time step $k>0$, whereas in the case $0 \leq \theta<\frac{1}{2}$ the time step $k$ must be sufficiently small.
Proposition 4.1. In the case of $\frac{1}{2} \leq \theta \leq 1$ assume that

$$
\begin{equation*}
0<C_{1}<2, \quad C_{2} \geq \frac{1}{2-C_{1}} \tag{4.2}
\end{equation*}
$$

and in the case of $0 \leq \theta<\frac{1}{2}$ assume that

$$
\begin{gather*}
\sigma:=k(1-2 \theta) \lambda_{A}<2  \tag{4.3}\\
0<C_{1}<2-\sigma, \quad C_{2} \geq \frac{1+\left(4-C_{1}\right) \sigma}{2-\sigma-C_{1}} \tag{4.4}
\end{gather*}
$$

Then the sequence $\left\{u_{h}^{m}\right\}_{m=0}^{M}$ of solutions of the $\theta$-scheme (3.5) satisfies the stability estimate

$$
\begin{equation*}
\left\|u_{h}^{M}\right\|^{2}+C_{1} k \sum_{m=0}^{M-1}\left\|u_{h}^{m+\theta}\right\|_{a}^{2} \leq\left\|u_{h}^{0}\right\|^{2}+C_{2} k \sum_{m=0}^{M-1}\left\|g^{m+\theta}\right\|_{*}^{2} \tag{4.5}
\end{equation*}
$$

Proof. Let

$$
X^{m}:=\left\|u_{h}^{m}\right\|^{2}-\left\|u_{h}^{m+1}\right\|^{2}+C_{2} k\left\|g^{m+\theta}\right\|_{*}^{2}-C_{1} k\left\|u_{h}^{m+\theta}\right\|_{a}^{2}
$$

We want to show that $X^{m} \geq 0$. Then adding these inequalities for $m=0, \ldots, M-1$ will obviously give (4.5).

Let $w:=u_{h}^{m+1}-u_{h}^{m}$, then $u_{h}^{m+\theta}=\left(u_{h}^{m}+u_{h}^{m+1}\right) / 2+\left(\theta-\frac{1}{2}\right) w$ and

$$
\left\|u_{h}^{m+1}\right\|^{2}-\left\|u_{h}^{m}\right\|^{2}=\left(u_{h}^{m+1}-u_{h}^{m}, u_{h}^{m+1}+u_{h}^{m}\right)=\left(w, 2 u_{h}^{m+\theta}-(2 \theta-1) w\right)
$$

By the definition of the $\theta$-scheme we have

$$
\begin{aligned}
\left(w, u_{h}^{m+\theta}\right) & =k\left(-A u_{h}^{m+\theta}+g^{m+\theta}, u_{h}^{m+\theta}\right)=k\left[-\left\|u_{h}^{m+\theta}\right\|_{a}^{2}+\left(g^{m+\theta}, u_{h}^{m+\theta}\right)\right] \\
& \leq k\left[-\left\|u_{h}^{m+\theta}\right\|_{a}^{2}+\left\|g^{m+\theta}\right\|_{*}\left\|u_{h}^{m+\theta}\right\|_{a}\right]
\end{aligned}
$$

This gives

$$
X^{m} \geq(2 \theta-1)\|w\|^{2}+k\left[\left(2-C_{1}\right)\left\|u_{h}^{m+\theta}\right\|_{a}^{2}-2\left\|g^{m+\theta}\right\|_{*}\left\|u_{h}^{m+\theta}\right\|_{a}+C_{2}\left\|g^{m+\theta}\right\|_{*}^{2}\right]
$$

In the case of $\frac{1}{2} \leq \theta \leq 1$ we now obtain $X^{m} \geq 0$ if the conditions (4.2) are satisfied.
In the case $0 \leq \theta<\frac{1}{2}$ we have by the definition of the $\theta$-scheme that $\left(w, v_{h}\right)=k\left(-A u_{h}^{m+\theta}+\right.$ $\left.g^{m+\theta}, v_{h}\right)$ yielding

$$
\|w\| \leq \lambda_{A}^{1 / 2}\|w\|_{*} \leq \lambda_{A}^{1 / 2} k\left(\left\|A u_{h}^{m+\theta}\right\|_{*}+\left\|g^{m+\theta}\right\|_{*}\right)=\lambda_{A}^{1 / 2} k\left(\left\|u_{h}^{m+\theta}\right\|_{a}+\left\|g^{m+\theta}\right\|_{*}\right)
$$

$\operatorname{since}\left(A u_{h}^{m+\theta}, v_{h}\right) \leq\left\|u_{h}^{m+\theta}\right\|_{a}\left\|v_{h}\right\|_{a}$ gives $\left\|A u_{h}^{m+\theta}\right\|_{*} \leq\left\|u_{h}^{m+\theta}\right\|_{a}$ and choosing $v_{h}:=u_{h}^{m+\theta}$ gives $\left\|A u_{h}^{m+\theta}\right\|_{*} \geq\left\|u_{h}^{m+\theta}\right\|_{a}$. Hence

$$
k^{-1} X^{m} \geq\left(2-C_{1}-\sigma\right)\left\|u_{h}^{m+\theta}\right\|_{a}^{2}-2(1+\sigma)\left\|g^{m+\theta}\right\|_{*}\left\|u_{h}^{m+\theta}\right\|_{a}+\left(C_{2}-\sigma\right)\left\|g^{m+\theta}\right\|_{*}^{2}
$$

Therefore we have $X^{m} \geq 0$ if conditions (4.3) hold.
Remark 4.2. The a-priori estimate (4.5) is, in a sense, the discrete analogue of the a-priori estimate (2.14). Note, however, that $\left\|g^{m+\theta}\right\|_{*}$ is not identical to $\left\|g^{m+\theta}\right\|_{V^{*}}$-in fact for $g \in V^{*}$, we have by $V_{h} \subset V$ that

$$
\left\|g^{m+\theta}\right\|_{*} \leq\left\|g^{m+\theta}\right\|_{V^{*}}
$$

Consider now the sequence $\left\{\widetilde{u}_{h}^{m}\right\}_{m=0}^{M}$ of solutions to the perturbed $\theta$-scheme (3.7a), (3.7b). We analogously define for $v_{h} \in V_{h}$ and $f \in V_{h}^{*}$

$$
\begin{equation*}
\left\|v_{h}\right\|_{\tilde{a}}:=\tilde{a}\left(v_{h}, v_{h}\right), \quad\|f\|_{\widetilde{*}}:=\sup _{v_{h} \in V_{h}} \frac{\left(f, v_{h}\right)}{\left\|v_{h}\right\|_{\tilde{a}}}, \quad \lambda_{\tilde{A}}:=\sup _{v_{h} \in V_{h}} \frac{\left\|v_{h}\right\|^{2}}{\left\|v_{h}\right\|_{\tilde{*}}^{2}} \tag{4.6}
\end{equation*}
$$

Due to the norm equivalence in Proposition 3.2, we obtain in the same way as in Proposition 4.1 with $\tilde{a}(\cdot, \cdot)$ in place of $a(\cdot, \cdot)$
Proposition 4.3. Assume that (3.8) holds with $\delta<1$. In the case of $\frac{1}{2} \leq \theta \leq 1$ assume that (4.2) holds. In the case of $0 \leq \theta<\frac{1}{2}$ assume that

$$
\begin{equation*}
\sigma:=k(1-2 \theta) \lambda_{\tilde{A}}<2 \tag{4.7}
\end{equation*}
$$

and that (4.4) holds.
Then the sequence $\left\{\tilde{u}_{h}^{m}\right\}_{m=0}^{M}$ of solutions of the perturbed $\theta$-scheme (3.7a), (3.7b) satisfies the stability estimate

$$
\begin{equation*}
\left\|\tilde{u}_{h}^{M}\right\|^{2}+C_{1} k \sum_{m=0}^{M-1}\left\|\tilde{u}_{h}^{m+\theta}\right\|_{\tilde{a}}^{2} \leq\left\|\tilde{u}_{h}^{0}\right\|^{2}+C_{2} k \sum_{m=0}^{M-1}\left\|g^{m+\theta}\right\|_{\tilde{*}}^{2} \tag{4.8}
\end{equation*}
$$

Remark 4.4. By the inverse estimate (3.4) and the norm equivalence (2.14) we have for $w_{h} \in V_{h}$

$$
\left\|w_{h}\right\|_{a} \leq C\left\|w_{h}\right\|_{\rho / 2} \leq C^{\prime} h^{-\rho / 2}\left\|w_{h}\right\|
$$

and therefore for $v_{h} \in V_{h}$

$$
\begin{align*}
\left\|v_{h}\right\|_{*} & =\sup _{w_{h} \in V_{h}} \frac{\left(v_{h}, w_{h}\right)}{\left\|w_{h}\right\|_{a}} \geq C h^{\rho / 2} \sup _{w_{h} \in V_{h}} \frac{\left(v_{h}, w_{h}\right)}{\left\|w_{h}\right\|}=C h^{\rho / 2}\left\|v_{h}\right\|  \tag{4.9}\\
\lambda_{A}^{1 / 2} & =\sup _{v_{h} \in V_{h}} \frac{\left\|v_{h}\right\|}{\left\|v_{h}\right\|_{*}} \leq C h^{-\rho / 2} \tag{4.10}
\end{align*}
$$

Hence there exists a positive constant $C_{*}$ independent of $h$ and $\theta$ such that the time-step restriction

$$
\begin{equation*}
k \leq C_{*} \frac{h^{\rho}}{1-2 \theta} \tag{4.11}
\end{equation*}
$$

is sufficient for stability (4.3). For $\rho=2$ and $\theta<\frac{1}{2}$ (e.g., forward Euler and the heat equation) this reduces to the well-known time-step restriction $k \leq C_{\theta} h^{2}$ for explicit schemes. For smaller values of $\rho$ the restriction is less severe, and in the limiting case $\rho=0$ condition (4.11) gives $k \leq C_{*} /(1-2 \theta)$ with a bound independent of $h$.

For the perturbed scheme (3.7) we can proceed in the same way and obtain using Proposition 3.2 that (4.11) is a sufficient condition for (4.7) (with a different value of $C_{*}$ ).

Remark 4.5. As $\theta$ tends to $\frac{1}{2}$ from below the bound on $k$ in the stability condition (4.3) tends to infinity, and for $\theta \geq \frac{1}{2}$ the stability holds with $\sigma=0$ and $C_{1}, C_{2}$ as in (4.4) for all values of $k$.

## 5 Convergence

Based on the stability results obtained in Section 4 and the consistency (3.8), (3.9) of the compressed form $\widetilde{a}(\cdot, \cdot)$, we shall now obtain optimal convergence estimates of the compressed $\theta$-scheme (sufficient regularity of the exact solution $u(x, t)$ in space and time provided). Throughout this section, we shall set

$$
\begin{equation*}
u^{m}=u\left(t^{m}\right) \in V . \tag{5.1}
\end{equation*}
$$

We will estimate the error

$$
\begin{equation*}
\widetilde{e}_{h}^{m}:=u^{m}-\widetilde{u}_{h}^{m} . \tag{5.2}
\end{equation*}
$$

To this end, we split $\widetilde{e}_{h}^{m}$ as follows:

$$
\begin{equation*}
\widetilde{e}_{h}^{m}=\underbrace{\left(u^{m}-P_{h} u^{m}\right)}_{\eta^{m}}+\underbrace{\left(P_{h} u^{m}-\widetilde{u}_{h}^{m}\right)}_{\xi_{h}^{m}}=\eta^{m}+\xi_{h}^{m} \tag{5.3}
\end{equation*}
$$

where $P_{h}: V \rightarrow V_{h}$ is the quasi-interpolant in (3.13) (realized as a truncated wavelet expansion, see Section 3.4 or $[9,3]$ for details).

As $\eta^{m}$ is a best approximation error, we focus now on $\xi_{h}^{m} \in V_{h}$.
Lemma 5.1. The $\left\{\xi_{h}^{m}\right\}_{m}$ are solutions of the $\theta$-scheme

$$
\xi_{h}^{0}=P_{h} u_{0}-\widetilde{u}_{h}^{0},
$$

for $m=0,1, \ldots, M-1$ and every $v_{h} \in V_{h}$ :

$$
\begin{equation*}
k^{-1}\left(\xi_{h}^{m+1}-\xi_{h}^{m}, v_{h}\right)+\widetilde{a}\left(\theta \xi_{h}^{m+1}+(1-\theta) \xi_{h}^{m}, v_{h}\right)=\left(r^{m}, v_{h}\right) \tag{5.4}
\end{equation*}
$$

where the weak residuals $r^{m}: V_{h} \rightarrow \mathbb{R}$ are given by

$$
\begin{equation*}
r^{m}=r_{1}^{m}+r_{2}^{m}+r_{3}^{m}+r_{4}^{m} \tag{5.5}
\end{equation*}
$$

with

$$
\begin{aligned}
\left(r_{1}^{m}, v_{h}\right) & :=\left(\frac{u^{m+1}-u^{m}}{k}-\dot{u}^{m+\theta}, v_{h}\right) \\
\left(r_{2}^{m}, v_{h}\right) & :=\left(\frac{P_{h} u^{m+1}-P_{h} u^{m}}{k}-\frac{u^{m+1}-u^{m}}{k}, v_{h}\right) \\
\left(r_{3}^{m}, v_{h}\right) & :=\widetilde{a}\left(P_{h} u^{m+\theta}, v_{h}\right)-a\left(P_{h} u^{m+\theta}, v_{h}\right) \\
\left(r_{4}^{m}, v_{h}\right) & :=a\left(P_{h} u^{m+\theta}-u^{m+\theta}, v_{h}\right)
\end{aligned}
$$

Proof. We note that (2.11) and $u \in C(\bar{J}, H)$ imply

$$
\begin{equation*}
\left(\dot{u}^{m+\theta}, v\right)+a\left(u^{m+\theta}, v\right)=\left(g^{m+\theta}, v\right) \quad \forall v \in V \tag{5.6}
\end{equation*}
$$

Since $V_{h} \subset V$, we get for every $v_{h} \in V_{h}$

$$
\begin{aligned}
& k^{-1}\left(\xi_{h}^{m+1}-\xi_{h}^{m}, v_{h}\right)+\widetilde{a}\left(\theta \xi_{h}^{m+1}+(1-\theta) \xi_{h}^{m}, v_{h}\right) \\
&=\left(\frac{\left(P_{h} u^{m+1}-\widetilde{u}_{h}^{m+1}\right)-\left(P_{h} u^{m}-\widetilde{u}_{h}^{m}\right)}{k}, v_{h}\right)+\widetilde{a}\left(P_{h} u^{m+\theta}, v_{h}\right)-\widetilde{a}\left(\widetilde{u}_{h}^{m+\theta}, v_{h}\right) \\
&=\left(\frac{P_{h} u^{m+1}-P_{h} u^{m}}{k}, v_{h}\right)+\widetilde{a}\left(P_{h} u^{m+\theta}, v_{h}\right)-\left\{\left(\frac{\widetilde{u}_{h}^{m+1}-\widetilde{u}_{h}^{m}}{k}, v_{h}\right)-\widetilde{a}\left(\widetilde{u}_{h}^{m+\theta}, v_{h}\right)\right\} \\
& \stackrel{(3.7)}{=}\left(\frac{P_{h} u^{m+1}-P_{h} u^{m}}{k}, v_{h}\right)+\widetilde{a}\left(P_{h} u^{m+\theta}, v_{h}\right)-\left(g^{m+\theta}, v_{h}\right) \\
& \stackrel{(5.6)}{=}\left(\frac{P_{h} u^{m+1}-P_{h} u^{m}}{k}-\dot{u}^{m+\theta}, v_{h}\right)+\widetilde{a}\left(P_{h} u^{m+\theta}, v_{h}\right)-a\left(u^{m+\theta}, v_{h}\right)=:\left(r, v_{h}\right) .
\end{aligned}
$$

The representation (5.5) of $\left(r, v_{h}\right)$ is now evident.
Lemma 5.1 implies together with the stability result Proposition 4.3 the following estimate for the $\xi_{h}^{m}$ :

Corollary 5.2. Under the assumptions of Proposition 4.3, we have

$$
\begin{equation*}
\left\|\xi_{h}^{M}\right\|^{2}+C_{1} k \sum_{m=0}^{M-1}\left\|\xi_{h}^{m+\theta}\right\|_{\widetilde{a}}^{2} \leq\left\|\xi_{h}^{0}\right\|^{2}+C_{2} k \sum_{m=0}^{M-1}\left\|r^{m}\right\|_{\widetilde{*}}^{2} \tag{5.7}
\end{equation*}
$$

Based on (5.5), we must estimate the $\left\|r_{j}^{m}\right\|_{\tilde{*}}, j=1, \ldots, 4$.
Estimate of $r_{1}^{m}$ : is based on Taylor expansion in $t$. Noting that for any $v_{h} \in V_{h}$

$$
\left|\left(r_{1}^{m}, v_{h}\right)\right| \leq\left\|k^{-1}\left(u^{m+1}-u^{m}\right)-\dot{u}^{m+\theta}\right\|_{*}\left\|v_{h}\right\|_{a}
$$

and

$$
k^{-1}\left(u^{m+1}-u^{m}\right)-\dot{u}^{m+\theta}=\frac{1}{k} \int_{t_{m}}^{t_{m+1}}\left(s-(1-\theta) t_{m+1}-\theta t_{m}\right) \ddot{u} d s
$$

we get

$$
\begin{align*}
\left\|k^{-1}\left(u^{m+1}-u^{m}\right)-\dot{u}^{m+\theta}\right\|_{*} & \leq k^{-1} \int_{t_{m}}^{t_{m+1}}\left|s-(1-\theta) t_{m+1}-\theta t_{m}\right|\|\ddot{u}\|_{*} d s \\
& \leq C_{\theta} \int_{t_{m}}^{t_{m+1}}\|\ddot{u}(s)\|_{*} d s  \tag{5.8}\\
& \leq C_{\theta} k^{+\frac{1}{2}}\left(\int_{t_{m}}^{t_{m+1}}\|\ddot{u}(s)\|_{*}^{2} d s\right)^{\frac{1}{2}} .
\end{align*}
$$

If $\theta=\frac{1}{2}$, an integration by parts gives

$$
k^{-1}\left(u^{m+1}-u^{m}\right)-\dot{u}^{m+\theta}=\frac{1}{2 k} \int_{t_{m}}^{t_{m+1}}\left(t_{m+1}-s\right)\left(t_{m}-s\right) \dddot{u}(s) d s
$$

and it follows that

$$
\left\|k^{-1}\left(u^{m+1}-u^{m}\right)-\dot{u}^{m+\theta}\right\|_{*}=C k^{\frac{3}{2}}\left(\int_{t_{m}}^{t_{m+1}}\|\dddot{u}(s)\|_{*}^{2} d s\right)^{\frac{1}{2}}
$$

Estimate of $r_{2}^{m}$ : here

$$
\begin{align*}
\left|\left(r_{2}^{m}, v_{h}\right)\right| & \leq C\left\|k^{-1}\left[\left(u^{m+1}-u^{m}\right)-P_{h}\left(u^{m+1}-u^{m}\right)\right]\right\|_{*}\left\|v_{h}\right\|_{\tilde{a}} \\
& =C k^{-1}\left\|\left(I-P_{h}\right) \int_{t_{m}}^{t_{m+1}} \dot{u}(s) d s\right\|_{*}\left\|v_{h}\right\|_{\tilde{a}}  \tag{5.9}\\
& \leq C k^{-1} \int_{t_{m}}^{t_{m+1}}\left\|\left(I-P_{h}\right) \dot{u}\right\|_{*} d s\left\|v_{h}\right\|_{\tilde{a}}
\end{align*}
$$

where we may now use the approximation property (3.3) of $P_{h}$ pointwise in $t$.
Estimate of $r_{3}^{m}$ : here we use the consistency (3.9)

$$
\begin{equation*}
\left|\left(r_{3}^{m}, v_{h}\right)\right| \leq C h^{p+1-\rho / 2}|\log h|^{\nu}\left\|u^{m+\theta}\right\|_{\mathcal{H}^{p+1}(\Omega)}\left\|v_{h}\right\|_{\tilde{H}^{\rho / 2}(\Omega)} \tag{5.10}
\end{equation*}
$$

By (2.14) and (3.11), we get $\left\|v_{h}\right\|_{\tilde{H}^{\rho / 2}} \leq C\left\|v_{h}\right\| \widetilde{a}$ and hence a bound on $\left\|r_{3}^{m}\right\|_{\tilde{*}}$.
Estimate on $r_{4}^{m}$ : Using (3.9) with $s=0$ and (3.3) gives

$$
\left|\left(r_{4}^{m}, v_{h}\right)\right| \leq C\left\|u^{m+\theta}-P_{h} u^{m+\theta}\right\|_{a}\left\|v_{h}\right\|_{\tilde{a}}
$$

and with the approximation property (3.3) we find

$$
\begin{equation*}
\left|\left(r_{4}^{m}, v_{h}\right)\right| \leq C h^{p+1-\rho / 2}\left\|u^{m+\theta}\right\|_{\mathcal{H}^{p+1}(\Omega)}\left\|v_{h}\right\|_{\tilde{a}} . \tag{5.11}
\end{equation*}
$$

Collecting the bounds (5.8)-(5.11) gives
Lemma 5.3. Assume that (3.8), (3.9) hold. If $u(x, t)$ is sufficiently smooth in $\bar{J} \times \bar{\Omega}$, we have for $r^{m}$ given by (5.5)

$$
\begin{align*}
\left\|r^{m}\right\|_{\tilde{*}} \leq C & \begin{cases}k^{\frac{1}{2}}\left(\int_{t_{m}}^{t_{m+1}}\|\ddot{u}(s)\|_{*}^{2} d s\right)^{\frac{1}{2}} \quad \text { for all } \theta \in[0,1] \\
k^{\frac{3}{2}}\left(\int_{t_{m}}^{t_{m+1}}\|\dddot{u}(s)\|_{*}^{2} d s\right)^{\frac{1}{2}} \quad \text { for } \theta=\frac{1}{2}\end{cases}  \tag{5.12}\\
& +C k^{-\frac{1}{2}} h^{p+1-\rho / 2}\left(\int_{t_{m}}^{t_{m+1}}\|\dot{u}\|_{\mathcal{H}^{p+1-\rho / 2}(\Omega)}^{2} d s\right)^{\frac{1}{2}} \\
& +C h^{p+1-\rho / 2}|\log h|^{\nu}\left\|u^{m+\theta}\right\|_{\mathcal{H}^{p+1}(\Omega)} .
\end{align*}
$$

Theorem 5.4. Assume that the consistency conditions (3.8), (3.9) hold. For $\theta \in\left[0, \frac{1}{2}\right.$ ) assume (4.7). Assume further that the approximation $u_{0, h} \in V_{h}$ of the initial data $u^{0}$ is quasioptimal in $L^{2}(\Omega)$. Then holds the following error estimate for the perturbed $\theta$-scheme with $\theta \in[0,1]$

$$
\begin{align*}
\left\|u^{M}-\widetilde{u}_{h}^{M}\right\|^{2}+k \sum_{m=0}^{M-1}\left\|u^{m+\theta}-\widetilde{u}_{h}^{m+\theta}\right\|_{a}^{2} \leq & C h^{2(p+1-\rho / 2)}|\log h|^{2 \nu} \max _{0 \leq t \leq T}\|u(t)\|_{\mathcal{H}^{p+1}(\Omega)}^{2} \\
& +C\left\{\begin{array}{l}
k^{2} \int_{0}^{T}\|\ddot{u}(s)\|_{*}^{2} d s \quad \text { for all } \theta \in[0,1] \\
k^{4} \int_{0}^{T}\|\dddot{u}(s)\|_{*}^{2} d s \quad \text { for } \theta=\frac{1}{2}
\end{array}\right.  \tag{5.13}\\
& +C h^{2(p+1-\rho / 2)} \int_{0}^{T}\|\dot{u}(s)\|_{\mathcal{H}^{p+1-\rho / 2}(\Omega)}^{2} d s .
\end{align*}
$$

Proof. Based on (5.3), we have for every $M \geq 1$

$$
\left\|\tilde{e}_{h}^{M}\right\|^{2}+k \sum_{m=0}^{M-1}\left\|\widetilde{e}_{h}^{m+\theta}\right\|_{a}^{2} \leq 2\left\{\left\|\eta^{M}\right\|^{2}+k \sum_{m=0}^{M-1}\left\|\eta^{m+\theta}\right\|_{a}^{2}\right\}+2\left\{\left\|\xi_{h}^{M}\right\|^{2}+k \sum_{m=0}^{M-1}\left\|\xi_{h}^{m+\theta}\right\|_{a}^{2}\right\}
$$

The first term can be estimated with the approximation property (3.3). The second term is treated using (3.11) and (4.8). We get

$$
\begin{aligned}
\left\|\xi_{h}^{M}\right\|^{2}+k \sum_{m=0}^{M-1}\left\|\xi_{h}^{m+\theta}\right\|_{a}^{2} & \leq\left\|\xi_{h}^{M}\right\|^{2}+k \widetilde{\beta}^{-1} \sum_{m=0}^{M-1}\left\|\xi_{h}^{m+\theta}\right\|_{\widetilde{a}}^{2} \\
& \leq \max \left\{1,1 /\left(\widetilde{\beta} C_{1}\right)\right\}\left\{\left\|\xi_{h}^{M}\right\|^{2}+C_{1} k \sum_{m=0}^{M-1}\left\|\xi_{h}^{m+\theta}\right\|_{\widetilde{a}}^{2}\right\} \\
& \leq \max \left\{1,1 /\left(\widetilde{\beta} C_{1}\right)\right\}\left\{\left\|\xi_{h}^{0}\right\|^{2}+C_{2} k \sum_{m=0}^{M-1}\left\|r_{h}^{m+\theta}\right\|_{\widetilde{*}}^{2}\right\}
\end{aligned}
$$

Using now the bound (5.12) for $\left\|r_{h}^{m+\theta}\right\|_{\widetilde{\mathscr{F}}}$, the quasioptimality of $u_{0, h}$ and the approximation property (3.3) with $s=0$ to estimate $\left\|\xi_{h}^{0}\right\|$ gives the assertion.

## 6 Approximate Solution of Linear Equations and Complexity

In order to compute the approximate solution $\tilde{u}_{h}^{m}$ in (3.7) for $m=1, \ldots, M$ we proceed as follows:

We first compute the mass matrix $\mathbf{K}$ in the wavelet basis with elements $K_{(l, j),\left(l^{\prime}, j^{\prime}\right)}$ where $O(N \log N)$ elements are nonzero. Note that for discontinuous multiwavelets (which can be used for $0 \leq \rho<1$ ) the mass matrix is diagonal.

Then we compute the compressed stiffness matrix $\tilde{\mathbf{A}}$ where $O\left(N(\log N)^{r}\right)$ elements are nonzero and $r=1$ if $\rho \in(0,2], r=2$ if $\rho=0$, see Proposition 3.4. If explicit antiderivatives of the kernel function are available (as is often the case), the total cost for computing the stiffness matrix $\tilde{\mathbf{A}}$ is $O\left(N(\log N)^{r}\right)$ operations. In other cases quadrature as described in [10] can
be used. This preserves the consistency conditions (3.8),(3.9) and the total cost of computing $\tilde{\mathbf{A}}$ is $O\left(N(\log N)^{r+d}\right)$ for $d=1,2$.

For each time step we have to solve (3.7b): We have to find $\tilde{w}_{h}^{m}:=\tilde{u}_{h}^{m+1}-\tilde{u}_{h}^{m} \in V_{h}$ satisfying

$$
\begin{equation*}
k^{-1}\left(\tilde{w}_{h}^{m}, v_{h}\right)+\theta \tilde{a}\left(\tilde{w}_{h}^{m}, v_{h}\right)=\left(g^{m+\theta}, v_{h}\right)-\tilde{a}\left(\tilde{u}_{h}^{m}, v_{h}\right) \quad \forall v_{h} \in V_{h} \tag{6.1}
\end{equation*}
$$

and then update $\tilde{u}_{h}^{m+1}:=\tilde{u}_{h}^{m}+\tilde{w}_{h}^{m}$. Let $\tilde{w}^{m} \in \mathbb{R}^{N}$ denote the coefficient vectors of $\tilde{w}_{h}^{m}$ with respect to the wavelet basis, and $\mathbf{K}, \tilde{\mathbf{A}} \in \mathbb{R}^{N \times N}$ the mass and stiffness matrices corresponding to $(\cdot, \cdot)$ and $\tilde{a}(\cdot, \cdot)$ in this basis. Then we obtain for $\tilde{w}^{m}$ a linear system $\mathbf{B} \tilde{w}^{m}=\tilde{b}^{m}$ with the matrix $\mathbf{B}=k^{-1} \mathbf{K}+\theta \tilde{\mathbf{A}}$ and a known right-hand side vector $\tilde{b}^{m}$.

For a standard finite element basis, the matrix $\mathbf{B}$ has a condition number of order $h^{-\rho}$ for small $h$ and fixed $k$. For the matrix $\mathbf{B}$ in the wavelet basis we can achieve a uniformly bounded condition number if we scale the rows and columns of $\mathbf{B}$ as follows: let $\mu_{l}:=\left(k^{-1}+\theta 2^{l \rho}\right)^{1 / 2}$ and let $\hat{B}_{(l, j),\left(l^{\prime}, j^{\prime}\right)}:=\mu_{l}^{-1} \mu_{l^{\prime}}^{-1} B_{(l, j),\left(l^{\prime}, j^{\prime}\right)}$. A similar scaling was proposed in [4]. Let in what follows $\|\cdot\|$ denote the 2 -norm of a vector, or the 2 -norm of a matrix.
Lemma 6.1. For the linear system $\hat{\mathbf{B}} x=b$ let $x_{i}$ for $i \in \mathbb{N}$ denote the iterates obtained by the restarted GMRES $\left(m_{0}\right)$ method with initial guess $x_{0}$. Then there holds

$$
\begin{equation*}
\left\|x-x_{j}\right\| \leq C q^{j}\left\|x-x_{0}\right\| \tag{6.2}
\end{equation*}
$$

where $C$ and $q<1$ are independent of $L, k, \theta$.
Proof. Throughout the proof, $C_{i}$ will denote generic positive constants independent of $h, k, m$, unrelated to $C_{i}$ above. Let $\mathbf{D}$ denote the diagonal matrix with entries $D_{(l, j),(l, j)}=2^{l \rho / 2}$. Because of the norm equivalence (3.12) we have for all $x, y \in \mathbb{R}^{N}$

$$
C_{1}\|x\|^{2} \leq x^{T} \mathbf{K} x, \quad x^{T} \mathbf{K} y \leq C_{2}\|x\|\|y\|
$$

Using the consistency conditions (3.8) of the wavelet truncation and (2.7), (2.8) we obtain

$$
C_{3}\|\mathbf{D} x\|^{2} \leq x^{T} \tilde{\mathbf{A}} x, \quad x^{T} \tilde{\mathbf{A}} y \leq C_{4}\|\mathbf{D} x\|\|\mathbf{D} y\|
$$

The constants $C_{j}>0$ are independent of $L$. Therefore $\mathbf{B}=k^{-1} \mathbf{K}+\theta \tilde{\mathbf{A}}$ satisfies with $C_{5}:=$ $\min \left\{C_{1}, C_{3}\right\}$ and $C_{6}:=\max \left\{C_{2}, C_{4}\right\}$

$$
\begin{gather*}
C_{5} x^{T}\left(k^{-1} \mathbf{I}+\theta \mathbf{D}^{2}\right) x \leq x^{T} \mathbf{B} x  \tag{6.3}\\
x^{T} \mathbf{B} y \leq C_{6}\left[k^{-1}\|x\|\|y\|+\theta\|\mathbf{D} x\|\|\mathbf{D} y\|\right] \leq C_{6}\left[x^{T}\left(k^{-1} \mathbf{I}+\theta \mathbf{D}^{2}\right) x\right]^{1 / 2}\left[y^{T}\left(k^{-1}+\theta \mathbf{D}^{2}\right) y\right]^{1 / 2} \tag{6.4}
\end{gather*}
$$

using the Cauchy-Schwarz inequality for the last estimate. Hence scaling with the diagonal matrix $\mathbf{S}:=\left(k^{-1} \mathbf{I}+\theta \mathbf{D}^{2}\right)^{1 / 2}$ yields with $\hat{\mathbf{B}}=\mathbf{S}^{-1} \mathbf{B} \mathbf{S}^{-1}$ and $\hat{x}:=\mathbf{S} x, \hat{y}:=\mathbf{S} y$ that

$$
\begin{equation*}
C_{5}\|\hat{x}\|^{2} \leq \hat{x}^{T} \hat{\mathbf{B}} \hat{x}, \quad \hat{x}^{T} \hat{\mathbf{B}} \hat{y} \leq C_{6}\|\hat{x}\|\|\hat{y}\| \tag{6.5}
\end{equation*}
$$

for all $\hat{x}, \hat{y} \in \mathbb{R}^{N}$ and therefore

$$
\lambda_{\min }\left(\left(\hat{\mathbf{B}}+\hat{\mathbf{B}}^{T}\right) / 2\right) \geq C_{5}, \quad\|\hat{\mathbf{B}}\| \leq C_{6}
$$

According to [6] the non-restarted GMRES method for the matrix $\hat{\mathbf{B}}$ therefore satisfies for the iterates $x_{m}$ and their residuals $r_{m}:=b-\hat{\mathbf{B}} x_{m}$

$$
\left\|r_{m}\right\| \leq\left(1-\frac{C_{5}^{2}}{C_{6}^{2}}\right)^{m / 2}\left\|r_{0}\right\|
$$

Because of $C_{5}\left\|x_{m}-x\right\|^{2} \leq\left(x_{m}-x\right)^{T} \hat{\mathbf{B}}\left(x_{m}-x\right) \leq C_{6}\left\|x_{m}-x\right\|\left\|r_{m}\right\|$ a corresponding estimate holds for the errors $\left\|x_{m}-x\right\|$.

Remark 6.2. If the operator $A$ is symmetric we can also use the conjugate gradient method for the symmetric matrix $\hat{\mathbf{B}}$. This will in general give the bound (6.2) with a smaller constant $q$ than the GMRES method.

Note that for a function $v_{h} \in V_{h}$ with coefficient vector $v$ and scaled coefficient vector $\hat{v}=\mathbf{S} v$ we have from (6.5) that with $b(u, v):=k^{-1}(u, v)+\theta \tilde{a}(u, v)$ and $\|v\|_{b}^{2}:=b(v, v)$

$$
\|\hat{v}\|^{2} \sim \hat{v}^{T} \hat{\mathbf{B}} \hat{v}=\left\|v_{h}\right\|_{b}^{2} .
$$

A functional $f_{h} \in V_{h}^{*}$ corresponds to a coefficient vector $f$ so that $\left(f_{h}, v_{h}\right)=f^{T} v$, and a scaled vector $\hat{f}=\mathbf{S}^{-1} f$ so that $\left(f_{h}, v_{h}\right)=\hat{f}^{T} \hat{v}$. Assume that we solve a linear system $\hat{B} \hat{v}_{*}=\hat{f}$ using $n_{G}$ steps of GMRES $\left(m_{0}\right)$, starting with initial guess 0 , yielding an approximation $\hat{v}$. We then have

$$
\left\|v_{h, *}-v_{h}\right\|_{b} \leq C q^{n_{G}}\left\|v_{h, *}\right\|_{b}
$$

and for the residuals $\rho_{h} \in V_{h}^{*}$ defined by $\left(\rho_{h}, w_{h}\right)=\left(f, w_{h}\right)-b\left(v_{h}, w_{h}\right)$ it holds that

$$
\left\|\rho_{h}\right\|_{b, *} \leq C q^{n_{G}}\left\|f_{h}\right\|_{b, *}
$$

where for $g_{h} \in V_{h}^{*}$ with $\hat{\mathbf{B}}_{s}:=\left(\hat{\mathbf{B}}+\hat{\mathbf{B}}^{T}\right) / 2$

$$
\left\|g_{h}\right\|_{b, *}:=\sup _{w_{h} \in V_{h}} \frac{\left(g_{h}, w_{h}\right)}{\left\|w_{h}\right\|_{b}}=\left(\hat{g}^{T} \hat{\mathbf{B}}_{s}^{-1} \hat{g}\right)^{1 / 2} \sim\|\hat{g}\| .
$$

We have with the inverse inequality

$$
\left(c_{1} k^{-1} h^{\rho}+\theta\right) \tilde{a}\left(v_{h}, v_{h}\right) \leq b\left(v_{h}, v_{h}\right) \leq\left(c_{2} k^{-1}+\theta\right) \tilde{a}\left(v_{h}, v_{h}\right)
$$

implying

$$
\left(c_{2} k^{-1}+\theta\right)^{-1 / 2}\left\|f_{h}\right\|_{\tilde{\mathbb{}}} \leq\left\|f_{h}\right\|_{b, *} \leq\left(c_{1} k^{-1} h^{\rho}+\theta\right)^{-1 / 2}\left\|f_{h}\right\|_{\tilde{\sim}}
$$

and

$$
\begin{align*}
\left\|v_{h, *}-v_{h}\right\|_{\tilde{a}} & \leq C \gamma^{1 / 2} q^{n_{G}}\left\|v_{h, *}\right\|_{\tilde{a}}  \tag{6.6}\\
\left\|\rho_{h}\right\|_{\tilde{*}} & \leq C \gamma^{1 / 2} q^{n_{G}}\left\|f_{h}\right\|_{\tilde{\mathcal{*}}} . \tag{6.7}
\end{align*}
$$

where

$$
\gamma:=\frac{c_{2} k^{-1}+\theta}{c_{1} k^{-1} h^{\rho}+\theta} .
$$

We now define the perturbed $\theta$-scheme with GMRES approximation as follows: Pick a value $m_{0} \geq 1$ for the restart number, e.g., $m_{0}=1$, and a value $n_{G}$ for the number of iterations. Let $\breve{u}_{h}^{0}:=u_{0, h}$. At each time step we want to want to find an approximation of $w_{h, *}^{m}$ satisfying

$$
b\left(w_{h, *}^{m}, v_{h}\right)=\left(g^{m+\theta}, v_{h}\right)-\tilde{a}\left(\check{u}_{h}^{m}, v_{h}\right) \quad \text { for all } v_{h} \in V_{h}
$$

which corresponds to a scaled linear system $\hat{\mathbf{B}} \hat{w}_{*}^{m}=\hat{b}^{m}$. We solve this system approximately with $n_{G}$ steps of GMRES $\left(m_{0}\right)$, using zero as initial guess, yielding an approximation $\hat{w}^{m}$ of the exact solution $\hat{w}_{*}^{m}$. We then let $\check{u}_{h}^{m+1}:=\check{u}_{h}^{m}+w_{h}^{m}$ where $w_{h}^{m} \in V_{h}$ is the function corresponding to the scaled vector $\hat{w}^{m}$. Then we have

Theorem 6.3. Assume that the consistency conditions (3.8), (3.9) hold. For $\theta \in\left[0, \frac{1}{2}\right.$ ) assume (4.3). Then the solution $\check{u}_{h}^{m}$ of the perturbed $\theta$-scheme with GMRES approximation satisfies the same error bound as $\tilde{u}_{h}^{m}$ in (5.13) if $n_{G} \geq C|\log h|$.

Proof. Let $\tilde{u}_{h}^{m}$ denote the solution of (3.7) (with all linear systems solved exactly), and let $\breve{u}_{h}^{m}$ denote the corresponding solution where the linear system (6.1) for each time step is solved with $n_{G} \operatorname{GMRES}\left(m_{0}\right)$ steps, using zero as initial guess. Let $\rho_{h}^{m} \in V_{h}^{*}$ denote the residual of the approximate GMRES solution $w_{h}^{m}$ : For all $v_{h} \in V_{h}$
$\left(\rho_{h}^{m}, v_{h}\right)=b\left(w_{h}^{m}, v_{h}\right)-\left(g^{m+\theta}, v_{h}\right)+\tilde{a}\left(\check{u}_{h}^{m}, v_{h}\right)=k^{-1}\left(\check{u}_{h}^{m+1}-\check{u}_{h}^{m}, v_{h}\right)+\tilde{a}\left(\check{u}_{h}^{m+\theta}, v_{h}\right)-\left(g^{m+\theta}, v_{h}\right)$
Then the difference $\zeta_{h}^{m}:=\check{u}_{h}^{m}-\tilde{u}_{h}^{m}$ satisfies $\zeta_{h}^{0}=0$ and a $\theta$-scheme of the same form as (3.7b)

$$
k^{-1}\left(\zeta_{h}^{m+1}-\zeta_{h}^{m}, v_{h}\right)+\tilde{a}\left(\zeta_{h}^{m+\theta}, v_{h}\right)=\left(\rho_{h}^{m}, v_{h}\right)
$$

where $\zeta_{h}^{m+\theta}=(1-\theta) \zeta^{m}+\theta \zeta^{m+1}$.
We now apply Proposition 4.3 and obtain for $l=0, \ldots, M$

$$
\begin{aligned}
E_{l} & :=\left\|\zeta^{l}\right\|^{2}+C_{1} k \sum_{m=0}^{l-1}\left\|\zeta_{h}^{m+\theta}\right\|_{\tilde{a}}^{2} \leq C_{2} k \sum_{m=0}^{l-1}\left\|\rho_{h}^{m}\right\|_{\tilde{F}}^{2} \leq C \gamma q^{2 n_{G}} k \sum_{m=0}^{l-1}\left\|g^{m+\theta}-\tilde{a}\left(\check{u}_{h}^{m}, \cdot\right)\right\|_{\tilde{\sim}}^{2} \\
& \leq C^{\prime} \gamma q^{2 n_{G}} k \sum_{m=0}^{l-1}\left(\left\|g^{m+\theta}\right\|_{\tilde{F}}^{2}+\left\|\zeta_{h}^{m}\right\|_{\tilde{a}}^{2}+\left\|\tilde{u}_{h}^{m}\right\|_{\tilde{a}}^{2}\right) .
\end{aligned}
$$

We denote the right hand side of (4.8) with $Q$.
Let us first assume that $\theta=0$ or $\theta=1$. In this case we choose $n_{G}$ large enough so that $C^{\prime} \gamma q^{2 n_{G}} \leq C_{1} / 2$ and obtain with $l=M$

$$
\begin{equation*}
\left\|\zeta^{M}\right\|^{2}+\frac{1}{2} C_{1} k \sum_{m=0}^{M-1}\left\|\zeta_{h}^{m+\theta}\right\|_{\tilde{a}}^{2} \leq C \gamma q^{2 n_{G}} Q \tag{6.8}
\end{equation*}
$$

since the terms $\left\|\zeta_{h}^{m}\right\|_{\tilde{a}}^{2}$ occur in $E_{M}$ and the terms $\left\|\tilde{u}_{h}^{m}\right\|_{\tilde{a}}^{2}$ occur in the left hand side of (4.8).
In the general case $\theta \in[0,1]$ we use

$$
\begin{aligned}
& \left\|\tilde{u}_{h}^{m}\right\|_{a}^{2} \leq C h^{-\rho}\left\|\tilde{u}_{h}^{m}\right\|^{2} \leq C h^{-\rho} Q \\
& \left\|\zeta_{h}^{m}\right\|_{\tilde{a}}^{2} \leq C h^{-\rho}\left\|\zeta_{h}^{m}\right\|^{2} \leq C h^{-\rho} E_{m}
\end{aligned}
$$

yielding

$$
E_{l} \leq C \gamma q^{2 n_{G}}\left(\left(1+h^{-\rho}\right) Q+k \sum_{m=0}^{l-1} h^{-\rho} E_{m}\right) .
$$

Therefore we have estimates of the form

$$
E_{0}=0, \quad E_{l} \leq \mu+\nu \sum_{m=0}^{l-1} E_{m}
$$

from which we easily get by induction

$$
E_{l} \leq \mu(1+\nu)^{l-1}
$$

Here we have $\nu=C \gamma q^{2 n_{G}} h^{-\rho} T / M$. We choose $n_{G}$ large enough so that $C \gamma q^{2 n_{G}} h^{-\rho} \leq 1$ and get $(1+\nu)^{M} \leq e^{T}$ and

$$
\begin{equation*}
E_{M} \leq C \gamma q^{2 n_{G}}\left(1+h^{-\rho}\right) Q e^{T} . \tag{6.9}
\end{equation*}
$$

Finally we have to choose $n_{G}$ large enough so that the right hand side in (6.8) or (6.9) is less than the bound in Theorem 5.4: If $k \leq 1$ we have $\gamma \leq C h^{-\rho}$, and therefore we need $n_{G}$ such that

$$
q^{2 n_{G}} h^{-2 \rho} \leq C h^{2(p+1-\rho / 2)}
$$

which is satisfied for $n_{G} \geq C|\log h|$ with $C>0$ sufficiently large, but independent of $h, k$.

Theorem 6.3 allows to estimate the complexity of the time-stepping scheme with incomplete GMRES solution of the linear systems.
Corollary 6.4. Given the compressed stiffness matrix $\tilde{\mathbf{A}}$, the additional work for computing $\check{u}_{h}^{1}, \ldots, \check{u}_{h}^{M}$ is bounded by $C M N(\log N)^{r+1}$ where $r=1$ for $\rho \in(0,2], r=2$ for $\rho=0$.

The total work of the algorithm (for computing the compressed stiffness matrix and performing $M$ time steps) is bounded by $C M N(\log N)^{r+1}$ operations if we use exact antiderivatives, and by $C N(\log N)^{r+d}+C M N(\log N)^{r+1}$ operations if we use quadrature for $d=1,2$.

We remark in closing that the powers of $\log N$ in these complexity estimates could be reduced by more elaborate compression techniques, see e.g. [13].

## Research Reports

No. Authors

01-07 T. von Petersdorff, C. Schwab

01-06 A.-M. Matache, C. Schwab
01-05 A. Buffa, R. Hiptmair, T. von Petersdorff, C. Schwab

01-04 R. Hiptmair, C. Schwab
01-03 C. Schwab, A.-M. Matache

01-02 A. Toselli, C. Schwab

01-01 A. Buffa, M. Costabel, C. Schwab

00-18 B.Q. Guo, C. Schwab
00-17 M.H. Gutknecht, S. Röllin

00-16 M.H. Gutknecht, S. Röllin
00-15 G. Schmidlin, C. Schwab Wavelet Galerkin BEM on unstructured

00-14 B. Cockburn, G. Kanschat, D. Schötzau, C. Schwab

00-13 O. Bröker, M.J. Grote, C. Mayer, A. Reusken

00-12 C. Lasser, A. Toselli

00-11 J. Liesen, M. Rozložník, Z. Strakos

00-10 C. Schwab, O. Sterz

00-09 M.H. Gutknecht, M. Rozložník
meshes by aggregation
Wavelet-discretizations of parabolic integrodifferential equations
Two-Scale FEM for Homogenization Problems
Boundary Element Methods for Maxwell Equations in Lipschitz Domains

Natural BEM for the Electric Field Integral Equation on polyhedra
Generalized FEM for Homogenization Problems
Mixed $h p$-finite element approximations on geometric edge and boundary layer meshes in three dimensions
Boundary element methods for Maxwell's equations on non-smooth domains
Analytic regularity of Stokes flow in polygonal domains
Variations of Zhang's Lanczos-Type Product Method
The Chebyshev iteration revisited Local Discontinuous Galerkin methods for the Stokes system

Robust Parallel Smoothing for Multigrid Via Sparse Approximate Inverses
An overlapping domain decomposition preconditioner for a class of discontinuous Galerkin approximations of advection-diffusion problems
On Convergence and Implementation of Minimal Residual Krylov Subspace Methods for Unsymmetric Linear Systems
A scalar boundary integrodifferential equation for eddy current problems using an impedance boundary condition
By how much can residual minimization accelerate the convergence of orthogonal error methods?
